Dear Kristinn:
I have used the AEA CIA for several years. It has worked well for me.
It is normally used as a swept frequency instrument so one may see SWR (or
other things) vs. frequency on its screen. I think that the other units
display information for one frequency at a time.

I work with antennas and networks where it is important to be able to
see the whole picture. You may not need that capability. Some people have
found the ability to record an antenna's swr vs. frequency to be valuable.

It gets cold in Michigan and in your country. You may wish to ask if
any of the units you list have problems when it is cold.

Let us all know what you decided.

>>>is too low at your site. You`re down in the Rio Grande valley.

So, if I took the 'rinky-dink' plastic loop antenna outside and placed it above the roof, it would work? Do I have to have a pair of wires for a lead-in or would just one do?

>>>The FM wire is likely about 2.5 feet long, or about 1/4-wavelength. Its
>>>impedance would be about 30 ohms near resonance.
>>>
>>>The loop is likely part of the AM tuned input circuit with an impedance
>>>of about 1000 ohms.
>>>

Take a look at http://www.nwham.net/w7zoi/rca_plugs.html for an example of
using RCA connectors at VHF.

Dear Sir,

Try the program "Vectors" at either of the following Web sites. By
plugging a few examples into the program, you will again understand
complex arithmetic.
http://zaffora.f2o.org/W9DMK/W9dmk.html
http://www.qsl.net/w9dmk/

The program does not run under an NT based system, such as Windows XP
or Windows 2000 but it will run fine in DOS under Windows 9x or
Windows ME.

Here is the short tutorial on complex arithmetic:

a1 + jb1 + a2 + jb2 = (a1 + a2) + j(b1 + b2)
The rule for subtraction follows the obvious complement to the above
example of addition.

In order to do complex multiplication and division it is easier to
convert first to polar form, as follows:

Magnitude of a + jb is sqrt(a^2 + b^2) and the Angle is arctan(b/a)

In Polar form the product of two vectors is the product of their
magnitues and the angle on the product is the arithmetic sum of the
two angles.

In Polar form the quotient of two vectors is the quotient of their
magnitudes with an angle that is the difference between the

numerator's angle and divisor's angle.

Example: 5@35 * 6@40 = 30@75

5@35 / 6@40 = 0.8333@-40
where @ means "at an angle of"

Nice looking installation but how will you mow the lawn next spring when the grass grows up thru your radial farm? Without the mower eating the radials?? I'd bury the things and forget them but I'm curious about how you plan to solve the problem.

Ed, I judge from from your writing you are an intelligent and educated USA voter.

The only thing which surprises me is how you manage to confuse slander with facts.

I take only one point from your message -

The ONLY terrorist attacks on the UK have ALL come from the Irish Republican Army - financed by charitable USA citizens, the CIA, and indirectly by USA governments regardless of political views.

Who needs enemies with 'special-relationship' friends like that?

USA citizens have no enemies who wish you harm. But you still suffer from "Reds Under the Bed." which, like WMD, are non-existent.

Reg.

Dear Gary:
Robert is correct in what he says in his tutorial. (Well, there is an obvious transcription error in the answer of the last example.) However, if you use a typical calculator to perform some of the calculations, there is a potential problem.

ArcTan(b/a) can, and eventually will, give you the wrong number. As an example: If a = 1 and b = 1, obviously the angle is 45 degrees, and the ArcTan function will present 45 degrees. Consider the case where a = -1 and b = -1: most calculator's ArcTan functions will still return 45 degrees. So, if using a typical calculator and the ArcTan function, make a sketch to estimate what the angle should be and correct the calculator's presentation accordingly.

The introduction of complex numbers, which were once part of "pure" math, and the concept of impedance made (and continues to make) circuits much more easy to deal with than was previously the case.

Enjoy, 73 Mac N8TT

The GAP (inside distance) between the Two Legs of the Matching Transformer is normally less than you can achieve using standard plumbing fittings especially on the upper frequencies. So the measurement is often doubled so to speak from 1/20th wavelength to 1/10th wavelength.
When increasing pipe diameter, don't forget the K-factor!
The 1/4 wave matching transformer will be slightly shorter, the 1/2 wave vertical will be shorter, and the GAP will be very slightly narrower.
Since you cut one leg of the transformer in conjunction with the vertical element as one piece, don't forget to shorten this pipe by both reductions in length.

> 73s de Kristinn, TF3KX

I have used three of these

MFJ-259B - OK while it was working, but it has failed twice. I do
not recommend!
Autek VA1 - Nice - but fiddley to use build quality not good
eats batteries!
AEA VIA - Very nice, the display makes on-site adjustments and checks
easy, ability to store and transfer data to a PC is useful
Solid build - won't run off NICAD/NIMH - it needs 12V!
N.B. I find the third party PC software better than the
official AEA software

At the time I attempted to review the AEA-CIA a few years ago, my worry was with the built-in firmware, which produced weird results in R-X mode (like, physically impossible).

The difference between the "amateur" and "professional" leagues for impedance measurement is that the professional Vector Network Analysers use a calibration procedure to compensate for their own internal errors. This boosts the measurement accuracy into a completely different league.

Of all the ones mentioned, only the N2PK and the TAPR designs can do
this. All the others really are playing in the amateur league.

Hi Kelly..
I am slowly but surely covering the radials with top soil out of our
pasture. I should be done in time so that once the grass needs to be mowed I
can set the deck for 2 inches (I usually cut at 1 inch) and the soil
covered radials will be fine..I hope!!!

So Reg, we are paranoid when it comes to "reds under the bed", but we are
unable to recognize "boyos under the bed"? Mr. Orwell would approve of your
doublespeak.

No Cecil.....
If you're without anguish you can't have any wine.
Unless Reg says so.

73 & Happy 2005
H.

PS and requisite antenna post:

Concrete pour for the tower in Monday at 7AM.
Leveled the base with a laser transit.
The yagi is a 4 element SteppIR, it will be at 50 feet on a 70 foot hill.
Finally! After 42 years of ham radio I get my beam-on-a-tower.

Richard
The tower's a 48' Trylon self-supporting affair.
The base, rebar cage, and additional rebar driven into the hole walls for positioning are all welded together.
The contractor made damn sure the base will remain plumb during the pour.
I intend to use 3 - 6 additional rods outside the cage attached to the legs with big cable.
Not familiar with the term "Ufer"?

Sure. Don't know if it would be worth the effort, but it's
certainly possible. You're basically trading 'coax' problems
for 'ladderline' problems, there's a differnece in the mechanics.
No idea if the benifits would be worth the effort...

Hi OM,

Concrete is conductive and with the large surface area presents quite
an electrode - the Ufer ground. Providing for a connection to its
metal interior insures you have access to this characteristic (and
with the rebar welded, insures that there will be no exploding
concrete at the J-Bolts due to current crowding if/when lightning
strikes).

Hi Richard
Lightning and the practicalities (no J-bolts, tower leg extension into the
concrete, holding the damn thing still during the pour) pretty much require
all the metal to be welded together. Then I'll put several good rods around
the base a few feet out.
I've seen lightning strike concrete; blew a 3 foot hole.

I've laid radials out over a lawn a number of times. The grass roots grow right over them in a short time, and the radials just disappear. No problems mowing. I do staple them down with pieces of electric fence wire bent into a U shape, to keep them down against the ground until the grass grows over them.

But this is an exceptionally good area for growing grass -- grass seed is the largest agricultural crop around here.

Seabat wrote:
"So, if I took the "rinky-dink" plastic loop antenna outside and placed it abive the roof, it would work?"

Most likely. Seabat said his car radio worked on the site. An a-c radio should normally be sensitive enough to operate on the same site.

An AM radio antenna does not need to be st high altitude as medium waves follow the earth`s curvature as they propagate in most cases. The existing metal roof in combination with the earth itself form a sandwich with the loop antenna in the middle. This has proved unsatisfactory. Seabat has "The Tin Riof Blues". It`s only necessary to get the AM antenna in effect out from under the metal roof.

I suspect that just extending loop wires would be fraught with problems. A variable capacitance in the radio likely tunes the loop. This loop in parallel with the capacitance makes a high impedance parallel-resonant circuit. Its impedance rises to about Q times the inductive reactance. This circuit is susceptible to upset due to stray capacitance from any long high-Z feeders. That`s why I proposed two additional loops to capture the signal and to transfer it to the radio. A tuned loop in the clear would capture in the signal, and the untuned loop would transfer the signal to the radio`s "rinky-dinky" plastic antenna loop on the radio shelf. These two loops would be interconnected with a twisted-pair of wires.

Seabat also wrote:
"I suppose an pld car antenna would work for the FM if placed up high, also?"

Yes. It`s exactly what I`ve long used as a 2-meter antenna. It is collapsed telescopically to about 19 inches. I added (4) equally spaced, drooping by 45-degrees, radials under the vertical radiator. They are also 19 inches long. With full forward power into the antenna, the reflected power is very low. The rig talks and listens very well.

For the FM broadcast band the elements would need to be lengthened to almost 30 inches.

Construction details are given in books such as the "ARRL Antenna Book"

Best regards, Richard Harrison, KB5WZI

Sorry to piggy-back on your post, but apparently, there *WERE* "reds under the bed. I would direct your attention to "Mask of Treachery" by John Costello. In it is detailed the penetration of MI-5 and MI-6 by the Cambridge gang of traitors. There is enough information in there to demonstrate that James Angelton was right, there was a considerable amount of KGB and GRU penetration of the CIA and the US Department of State. One of FDR's personal assistants was probably a KGB or GRU spy. Another good book is "Operation Solo" by John Barron. It details the life of a top CPUSA operative named Morris Childs who was an FBI spy. The Soviets funneled (documented) millions of dollars into the CPUSA.

Chuck asks:
> Are the radiation resistances for various Hamstiks published
anywhere?

Since the Hamsticks are approximately 8 feet long, these values from the ARRL Antenna Book should be in the same ballpark. 75m ~ 0.8 ohms, 40m ~ 3.0 ohms, 30m ~ 5.8 ohms, 20m ~ 11.0 ohms, 17m ~19 ohms, 12m ~ 29 ohms.

The key question seems to be: Where you live, which is harder - growing
a lawn, or mowing it?

If your lawn seems to grow faster than you can mow it, you can safely
lay the radials on top... and then let the grass do all the hard work.

Some years ago, a friend laid a radial system of 1in wide metal strips,
simply stapled down onto his flat, dense English lawn. Within a year,
you couldn't see the strips from any distance away. After about five
years they were completely covered.

I&#65533;m planning to build a new multi-band antenna, and found something
entirely new to me , an antenna like a w3dzz but with &#65533;stubs&#65533;instead of
traps. Take a look at www.g3ycc.koroo.net/lattin.htm
Should be possible to build with wires and spacers?
Anyone know (and uses!) this antenna?
I also have been thinking of a T2FD-ant, tips on
inductance-free resistors tnx, someone built a smart T2FD?
(smart meaning simple solutions for R and feeding (coax))
Comments please!

Last I heard, no one has independently verified that it works as
advertised. A/B comparisons to a dipole would be nice as would a
simulation model.

Just noticed that the URL should be:

http://www.g3ycc.karoo.net/lattin.htm

Here's an earlier quote that might interest you:

>Lee Carkenord KA0FPJ Denver CO wrote: >>This time we used the
much sturdier ladder line (for traps/radiator) as a starting point.
Mechanically, this was a fairly robust device. Electrically, it was
the same as our previous attempt. We spent a lot of time with it.
Cut up a lot of wire. We finally reluctantly gave up. We _WANTED_
it to work, but we were just not able to get anything accomplished.
Again, we felt that we were never close to having a workable, 50 ohm
coax-fed, multi-band antenna.<<

Hi Pegge,

This is one of those designs that has elements of authenticity, but
poor implementation. In other words, it does not work in the way it
is described (and is notorious for not working at all).

The elements of authenticity are with stubs as you have noted. Open
and closed stubs do replace lumped circuits of inductors and
capacitors to function as traps and loads. The poor implementation is
that you do not construct stubs to replace those traps or loads in the
ways commonly described (and the added stringer wires only compound
the poor logic).

Every implementation I've observed consists of building the stub
without feeding it across its mouth, but along its body. This makes
the other half of the stub (the total structure now no longer a stub)
simply a parasitic wire with no particular merit.

Proper stubs on VHF/UHF antennas that can support them, give the
proper orientation of being at 90ï¿½ to the radiating structure (unlike
the Lattin). Sometimes the stub is compressed by folding or rolling
its length around the antenna, but the mouth is always in series with
the radiating element. In other words (use fixed font to view one
half of a dipole, source on the left as ï¿½):
ï¿½----------------- ------------------
| |
| |
| |
--
But not:
ï¿½--
|

To build the Lattin style with mouth fed stubs (and probably not
functioning as traps), would require three wire constructions:
ï¿½--------------------------
|

|

Which is now verging on the concept of a Franklin Antenna which you should research in place of Lattin styles. However, I would point out that the Franklin is a single band gain antenna. I only mention it to study as it gives a better theoretical description (and works because of it).

Three years ago I laid some RG-213 in the grass across my back yard and into the shack. It's
close enough to the ground that my mower doesn't touch it, and after one year
you couldn't even see it! It's about a 50 ft run and has stood up to two Alberta
winters with no signs of deterioration. I have also run radials in the grass and
was surprised at how fast they disappeared into the roots -- I didn't use any
staples -- too lazy!

A stub is an open-circuited or short-circuited section of transmission line. It can be a series stub or a parallel stub. It can be inductive, capacitive, or resonant depending upon length. At a single frequency, a stub can replace an inductor or capacitor and/or cause a change in impedance, i.e. a change in the voltage to current ratio. (Not to be confused with software stubs.)

The URL above is in error - it should be
www.g3ycc.karoo.net/lattin.htm

I have built such an antenna, but I used the 1 inch wide window line
(450 ohm) instead of the 300 ohm foam filled. This should have 0.95
velocity factor instead of 0.8, so the sections had to be
proportionally longer. My dimensions are as follows:

A = 9.9 meters
B = 5.0 meters
C = 2.5 meters
D = 2.9 meters

I built it to be used as a hanging vertical fed against ground, but
have not been able to get it hung properly as yet. At the moment, for
test purposes only, it is hanging in a catenary with the high end
about 15 ft above ground and the feed point is at ground level and fed
agains a good earth ground.

Resonances occur at 2.96 MHz, 6.52 MHz, 10.12 MHz, 12.5 MHz, 19.46
MHz, and 28.57 MHz as measured with an MFJ Antenna Analyzer. I explain
the low frequency resonances being lower than the design values as
being due to the fact that the antenna is almost horizontal and not
very high. If I can get it hung vertically, I expect it exhibit
resonances closer to the design values.

Thanks for sorting out the link.
Looks like a sound design.
Careful construction and measurement should yield a successful antenna.

Hi, all concerned:

www.g3ycc.karoo.net/lattin.html

is the corrected url.

If the dimensions are added up, the overall physical length approaches that of an 80M dipole. "Loading-effect" of the "fat-wire" dipole could be helped along if needed on 80M by additional wire length past A.

The A-stubs reduce the electrical lengths each side to overall 40M-dipole-size.

Ditto B-stubs on 20M.

Ditto C-stubs on 15M.

Changing the D-lengths to single wires, or shorting both inner ends, completes the 10M-dipole section.

Editorial comments:

The feed shown is "incorrect". Stubs at D are not needed, unless one wishes to add higher-frequency capability. Single wires are sufficient for the 10M portions of the dipole.

This Lattin antenna is not easily constructed or tuned, and it reminds me of something from the category of solutions running around looking for problems.

The current amateur application that I can think of which is done "properly" is the KLM h-f tribander. The stubs are of open-construction, and the first stubs, at the outside end the 10M portions of the antenna elements, can be seen easily, even in pictures.

Source record: 84390

While a stub can be made to act just like a resonant circuit at one frequency, and almost like one over a range of frequencies, it behaves quite differently at frequencies which are quite different from the resonant frequency -- such as on other bands. That is, the stub will act like a trap at one band, but not at all like a conventional trap at other bands. There's no inherent disadvantage in this, but it means you can't simply replace traps with stubs and have the antenna behave the same as before on all bands. Considerable redesign or adjustment might be required.

Another caution is that a stub is likely to have lower Q than a good trap. This can, but doesn't necessarily, result in significant loss on some bands. Careful modeling can give a pretty realistic idea of the loss you can expect.

Finally, if you model a stub in an application like this, you can't use NEC or EZNEC transmission line models, because the currents on the wires aren't equal and opposite -- you have to make the stub models out of wires. And be sure to include wire loss if you want the model to give a realistic assessment of loss.

Dear Dave,

I could certainly be wrong, but my calculations indicate that the "C"
stubs are designed to produce a trap for 10 meters - not 15 meters.

The feed shown is at worst ambiguous. Actually, according to my
measurements and according to common sense, the "D" stubs perform no

useful function. You can feed from either wire or you can twist those two wires together and feed jointly - same result.

I think the purpose in carrying the same material all the way through the design was the real point, but section D is just wire for the 10 meter dipole. There may have been some subtle reason for having a stub at position D that resonates at 25 MHz, but I don't see it.

Why are power limits specified so low for dual-band and tri-band HT
rubber duck antennas? The conductors in the couple I saw surgerized
looked like they could handle lots more.

I am considering a mobile magnetic base that accepts SMA antennas,
but am deterred by the low limits for the duckies I would want to use.

The concept is that you transfer your ducky from the HT to the roof
when you get into your car. No problem with just the HT but not so
good with a QRP amp that outputs 30 watts.

21st Century E-Commerce Money Making Formula

This works better than letters & it's all electronic!

Posted By: E'Sean Date: Wednesday, 21 July 2004 eMoney Making Formula

"This is so awesome. Try it. The more people that do it the better."

"I turned $3 into $14,706 within the first 30 days of operating the business plan that I am about to reveal to you free of charge."

If you decide to take action on the following instructions, I will personally GUARANTEE that you will enjoy a similar return!"

Please do not be skeptical about this program.

At least think about it for a few days.

Otherwise you will be throwing away over $10,000 in cash!

Dear Friend, My name is Mark Sutton. I was laid off from my job in August of 2001 At that time I wasliving beyond my means and in serious debt. Several debt collectors were hounding me on an almost daily basis, and this consequently started a chain reaction that ended with the repossession of my car and then my home. As you can probably imagine, my prospects looked pretty bleak. Then, in March of 2002, I received a short and simple email telling me how to make over $10,000 at a time.

I ignored it because of course, I was skeptical.

However, I didn't delete that email because something about it rang true to me, and I was desperate to know whether it was possible to make that amount of money in such a short space of time. By this time, I was even deeper in debt, and I had just about reached the point of despair. I finally realized that I had absolutely nothing to lose by having a go at the plan offered to me in that email.

And apart from that, I just couldn't stop myself from thinking "What if it actually works?" Therefore, I put my doubts to one side and I went ahead and followed the simple instructions given in that email. It took me less than 30 minutes

to complete and it cost me no more than $3. And yet, by the end of 2002, I was able to book the family holiday of a lifetime in Miami, and

I bought a brand new Audi A8 with hard cash. And in the autumn of 2003, I purchased a tidy semi-detached home for no less than $125,000. And yet,

I don't owe a single penny to anyone!

To date, I have made exactly $392,718. My accountant has drawn up a cash-flow forecast in which he predicts that, within the next 24 months, I will become a millionaire just through this one business alone. Even now as I write this, I find it strange to come to terms with the fact that, like most people, I've worked hard and struggled all my life just to 'get by' and then something ridiculously simple drops into my lap and immediately turns my life around completely.

When I think back to all the similar emails I had previously deleted, it makes me shudder, because now I know just how close I came to missing out completely.

What did it say in that email?

What were those simple instructions that enabled me to amass so much money in so little time?

Well, if you'll read on, all will be revealed!

The business plan I am about to share with you works perfectly every single time. I've never made less than $10,000 from it on each occasion. Let me assure you that this is a LEGITIMATE BUSINESS OPPORTUNITY, a perfectly legal moneymaking enterprise. It does not require you to sell anything. It does not require you to speak to your friends, family or anybody else (unless you want to). In fact, you do not need to come into contact with any people whatsoever. Anyone with a pulse can become successful and make their fortune with this system. If you believe that 'every dog has his day', then follow the simple step-by-step plan exactly as it is set out below. If you do this and this alone, I GUARANTEE that within the next 30 days you will receive over $10,000 in cash via your PayPal account. I know that this must sound like an outrageous claim, particularly if you've never had possession of this sort of money before, but believe me, this business works like nothing else you may have seen before in your life!

By following the simple 3-step plan set out below, within a few short weeks your life will be transformed beyond all recognition! Please do not allow your initial skepticism to deprive you of certain financial success. If you decide not to take advantage of this life-changing opportunity, I would like you to know that I sincerely respect your decision and I understand that you will have your reasons. I therefore wish you the very best of luck for the future. I am able to say this with absolute sincerity because, as you will see, if you decide to work this plan, I will not receive any financial compensation from you whatsoever. After all, I am sharing this system with you for free. However, remember life is short. Nobody has ever said that you can't have the financial freedom to do what you want to do, when you want to

do it.

But you must first pay the price. The price here is action; it's as simple as that!

I'm very proud to be able to say that I've fulfilled my duty to my wife and children by securing their financial future in a very uncertain world, and I don't believe that any price is too great to pay for such peace of mind. THIS IS THE CHEAPEST, FASTEST & EASIEST WAY TO MAKE MONEY ONLINE - PERIOD!

There are a lot of companies out there offering to put you in your own business, but I'm so certain you will make a SERIOUS INCOME with what I am going to tell you that I'm willing to roll up my sleeves and help you begin - RIGHT NOW!!

Remember, I am not asking you to send me a single penny for the lucrative business project I am about to share with you. In addition, you will not be asked to buy anything or sacrifice your free time. You will make some fast and easy cash, using just a copy of this email and the simplest and most popular Internet payment system in existence!

You have most likely seen or heard about this project on TV programs such as 20/20 and Oprah Winfrey, or you may have read about it in the Wall Street Journal. If not, here it is below - revealed to you in step-by-step detail. This program is by no means new. It has been in existence in many forms for at least ten years. But in the early days, it required a lot more time and effort, as well as an outlay of a few hundred dollars. However, thanks to PayPal and the Internet, the outlay is now virtually ZERO! On top of that, the entire process is FASTER, EASIER, and MORE LUCRATIVE than it has EVER been! If you're already running a home business, you can easily do this one along with it. If not, this is the FASTEST and EASIEST way to earn serious money online that you've ever seen so far in the history of the Internet! This program works no matter what country you are in, or what currency you use. It doesn't matter how old or how young you are. And you certainly won't need any special knowledge or talent. You won't need to run a website, or make phone calls, or make photocopies, or send out letters through the mail, or pay for advertising, etc.

The only things you will need are: * An email address * A Premier or Business PayPal account with at least $3 deposited in it * 30 minutes of your time

This program takes just half an hour to set up. After that, there is absolutely no work whatsoever to do on your part. And yet, you will stand to gain many thousands of dollars within the next few weeks from those 30 minutes of easy work! Yes, I know, it sounds too good to be true! I thought exactly the same thing myself until I actually tried it out!

Even if you are already involved in another program, stay with it, but do yourself a big favour and DO THIS ONE as well. You have absolutely

NOTHING to lose, but you stand to gain a LIFE-CHANGING amount of money within the next few weeks! In fact, there is NO LIMIT to the amount of income you can generate from this one single business program!! The facts are simple: If you need to make a few thousand dollarss REALLY FAST, then this program is the way to do it! It's the CHEAPEST, FASTEST, EASIEST, and MOST LUCRATIVE program you will ever participate in!

Please be sure to read all of this page . . . take your time, come back to it . . . go over and over it, you won't be sorry, I can certainly promise you that! If you don't have time to read all of this now, then save this page, or add it to your Favorites list, so you can come back to it later. ALL YOU NEED IS A PAYPAL ACCOUNT & AN EMAIL ADDRESS! Just about everyone has heard about "PayPal" (if you haven't you will soon!) and when I came across this concept I knew it would work because, as a member of PayPal, I had already experienced their efficiency and excellent standing. PayPal is the simplest method of making and receiving payments online that anyone has ever seen! Anyone with an email address can join for FREE! Once you have a PayPal account, you can send and receive credit card payments to or from anyone - anywhere in the world! Please read further before you go there... You can complete this whole process within just half an hour and you will NEVER forget the day you decided to do so!!!

NEED PROOF? Here are just 3 testimonials from the countless individuals who decided to invest nothing more than $3 and half an hour of their time to participate in this program:

" What an amazing plan! I followed your instructions just 3 weeks ago, and although I haven't made 10 grand yet, I'm already up to $6,135. I'm absolutely gob smacked." Alan Humphries , Leicester

"This is Lisa. Well, what can I say?... THANK YOU SO MUCH! I sent 40 e-mail's out like you said and then I just forgot about the whole thing. To be honest, I didn't really think anything would come of it. But when I checked my paypal account a week later, there was over $3,000 in it! After 30 days I now have over $11,000 to spend! I can't thank you enough!" Lisa McDonald, Northampton

" I was shocked when I saw how much money came flooding into my paypal account. Within 3 weeks my account balance has ballooned to $7,449. At first I thought there had been some sort of error with my account!" Richard Barrie , Cirencester

Just a few months ago, each of these people were doing the same thing as you are at this very moment - reading this! But because they decided to follow the simple instructions given below, they are now considerably better off as a result. And there's no reason whatsoever why you can't share in this success. You've got nothing to lose, and EVERYTHING to gain! Let's get started, just follow the instructions exactly as set out below and then prepare yourself for a HUGE influx of cash over the next 30 days!

HERE'S WHAT YOU NEED TO DO. . .

STEP 1

Ok, if you're not already a PayPal user, the very first thing you need to do is use the PayPal link below and SIGN UP. It takes just two minutes!
https://www.paypal.com/us/mrb/pal=ZVR6VDMJUDB5Y

Be sure to use this link so you can sign up for a free PREMIER or BUSINESS account. You'll need to have a PREMIER or BUSINESS account (and not a PERSONAL account) otherwise you won't be able to receive credit card payments from other people.

STEP 2

It is an undeniable law of the universe that we must first give in order to receive. So the first thing to do when you have your Premier/Business PayPal account is to IMMEDIATELY send a $3 payment from your PayPal account to the FIRST email address in the list below, along with a note saying: " Please add me to your mailing list." Be certain to add this note, as this is what KEEPS THIS PROGRAM LEGAL. Instructions on how to send a payment are under "SEND MONEY" at the Paypal Site. It's so Easy!! When you send your $3 payment to the first address in the list, do it with a great big smile on your face because "as you sow, so shall you reap!"
<>Here's the current list
(1)bmedsker@cablespeed.com (2)disbellj@midsouth.rr.com (3) moty7ellek@adelphia.net (4)spontaniuz@msn.com (5)dholla@msn.com

After you have transferred a $3 payment to the email address at the top of the list, something very eerie happens. It gives you an indescribable, overwhelming sense of certainty, belief and conviction in the system. You've just proved to yourself that, because you have done it, there must be a great number of other people ready to do exactly the same. Thus you have now seen for yourself, first hand, that this business actually works!

STEP 3

Once you've sent a $3 payment to the address at the top of the list (along with a note,please add me to you mailing list! - this is VERY important!), the next thing you need to do is to obtain a copy of this email message, as you'll be sending it out to at least 40 people.

The copy that you will send out will contain YOUR unique PayPal referral URL and YOUR email address at number 5 in the list - having deleted the address at Number 1 in the list, and moving the others up a position. The easiest way to do this is to:

(A) Go to your toolbar (at the very top of the screen) and select EDIT and then SELECT ALL.

(B) Go to the toolbar again and select EDIT and then COPY.

(C) Start (compose) a new email message (PLAIN TEXT so everyone can view it!).

(D) Fill in your email address and subject line.

(E) Go to EDIT and PASTE to paste this text into your new email message. Now you can edit this email message in any way you want!

The first thing to edit are the email addresses in the list above. Delete the top email address, and then move the others up a position, and then add YOUR email address to the bottom of the list (the number 5 position). Be sure to use your email address that is associated with your PayPal account. But DO NOT forget to send $3 via PayPal (along with your note!) to the email address at position number 1 before deleting it! Don't be tempted to add your name to position 1 in order to earn money fast! It doesn't work like that!

If you do that, you will ONLY reach the people you directly send emails to, and then your name will be immediately removed from the No.1 place and you won't reach thousands of people! But, if you add your name to the Number 5 position, there will be literally thousands of people receiving and sending email's later - when your name is at the Number 1 spot!!!

Now you need to edit the PayPal referring URL (shown above in Step 1) with your own PayPal referring URL. You can find YOUR referring URL at Paypal after you join. Just look at the bottom of the first page once you sign into Paypal, and click on the "referrals" link. You will be given a referring URL similar to the one above, except the code number at the end will be different. Simply delete the current PayPal referral URL in Step 1 above, and replace it with your PayPal referral URL.

(F) Once you've edited your email message as outlined above, send out a minimum of 40 copies of this email. You can advertise it any way you want to But no spam.
Best of luck and remember to play fairly and honestly and this will really work

Yours Truly
Neo-Tycoon

>Why are power limits specified so low for dual-band and tri-band HT
>rubber duck antennas?

Hi Ken,

I think you've got the cart before the horse. Rubber Duck antennas are usually associated with low power radios; not low power with Rubber Ducks. In other words, the limitation comes with the radio, not the antenna.

Now, on the other hand, performance invariably improves when you replace the Rubber Duck with a standard antenna (however that may be achieved). The reasons may be manifold, but I would figure issues of loss would be found in the soft tissues of the antenna mast (a hand/arm) or nearby obstructions (skull/torso).

Let's just flip the argument, and speculate how well a mike mounted Rubber Duck for a 100W rig would be accepted in the marketplace. Anyone worried that the Duck might melt has misplaced priorities. (Reminds me of last week's Simpsons where Homer discovers a walk-in Microwave Oven where he proceeds to cook his popcorn.)

Well, I suppose most of those fantasies above are restricted to single band antennas. The dual banders would undoubtedly contain components that were designed to feed or present a Hi-Z antenna, and would thus face a rather stiff voltage - hence the limits on power.

I got blank screens when I looked at the two posts about stubbs. I may have one, I have a W9INN multiband dipole and it has several "non traps" I can't find the liturature on the thing so don't know what he called the things, and W9INN is now a silent key.

I am trying to get the best performance from my Ten Tec RX-320 when it is connected to my shack's QRP 40M extended double zepp (176 ft overall, fed with 300 ohm twinlead).

Performance on HF improved when I inserted an LDG 4:1 balun. I substituted a $3 TV balun (300/75) and the improvment remained.

However, I noticed that VLF/LF -- for which my radio has the AMRAD mod -- has gone more or less deaf. I can't even hear Loran on 100 kHz; without the balun it was 59. BCB -- already attenuated with an I.C.E. BCB filter but also 59 -- has also gotten worse.

Why would a balun made for high frequency impede low frequency (i.e. below 1.5 kHz)?

The N2PK would be the best, except that it only runs when
connected to a laptop. I don't have a laptop, and if I did, I
wouldn't want to carry it out to the antennas, and furthermore,
laptop displays are usually not visible outdoors during daylight.
All the others don't work if you have nearby AM BCB stations
like I do.

Still looking for an antenna analyzer I can really use.

Some of it has to do with the rather wildly variable impedance that an HT antenna will present, but in general, HT's aren't high power devices, pretty much by definition.

anyone know a simple 10khz jump feature mod for this PLL?
I have a brand new older model Midland CB 40 channel that I would
like to do this to..I know all the other "band" mods, but do not wish to do
them.
A buddy 35 miles away has a birthday on the 20th of January.
I offered him a AM/SSB radio, but he does not like the SSB mode. He is going
blind and
a simple switch to go from 27.185mhz to a very quiet 27.195 will be a
tremendous
blessing. I have done tons of searches and came up with only one that was
worth trying.

http://www.geocities.com/y40002000/plowboy2.html

if someone here has tried this and it WORKS , let me know BEFORE I open this
baby up.
Email me at horseflygk@att.net

I don't post here often, when I do I am generally giving away info for you
guys. My goal before I get old is to get my Ham ticket, which will take all
of month of studying or less If I cram. Been in electronics long
time....my HR2510 takes me in the 10-11 meter bands from 26.000mhz to
29.000mhz AM, FM, CW, USB, LSB..
.

Ken,
When I was reading articles on home-rolled baluns the "TV balun" was
referenced a few times in regard to use on HF. From what I recall,
they started to poop out around 10 MHz and got worse as the frequency
lowered which would explain why you're okay on HF but worse on
MW/LF/VLF. From what I recall it has to do with the fact that those
"TV baluns" just don't have a sufficient number of windings to "prime
the electron pump" at lower frequencies. I've taken a couple apart to
use the torroid for a 9:1 transformer and the winding ratio on each
was 2:1. Are you okay on the lower frequencies with the LDG balun?
If so then at least it's narrowed down to one component.
Perhaps it's time to bust open the balun, remove the torroid and roll
your own. Use #26 or smaller enamel wire (magnet wire) and a 20:10
winding ratio for your 4:1 balun and you may find your problem on the
lower frequencies goes away ..... or at least isn't as bad.

Hope that helps,
Howard

Source record: 84401

Wellll..

Legalities aside and being strictly technical...

The PLL02A is a binary programmable divider device and from memory a logical change of the least significant bit is 10kHz.

I don't remember the pin numbers off hand but if you probe around with a multimeter you will find that pin that changes state every 10kHz. Make sure you pick a range where the channels really do change 10kHz at a time (eg 16 through 19).

With some logical thinking and the knowledge that either side of 27.195 the state will either be high or low, you will find that setting the selector to 185 or 205 and changing that pins state will change to 195. You will be able to do the same thing for the other "gaps" at ch3-4, 7-8, 11-12, & 15-16.

So how do you change the state? I cant remember whether the chip has pull-ups or pulldowns and which way the channel selector goes. I guess you should break the connection and insert a switch with centre to the chip. Once side you should reconnect to the original wiring and the other to a pullup or down as needed.

I don't suggest you go pulling a crystal off frequency as outlined on the URL you posted. You should note by the way that the mod above will give a 10kHz change on roughly half the channels. The rest wont change at all.

My reply address is bogus. If you wish to reply substitute bcnuup for bcnntp

Try http://www.cbsite.nl/modif/onderdelen/pll02a.htm - It took me 30 seconds to find.

Cheers Bob VK2YQA

> 73, Cecil http://www.qsl.net/w5dxp
>

In their most common form stubs are multiples of a quarter wavelength
and, at least at VHF and higher, consist of a piece of coax cable.

A stub that is an odd multiple of a quarter wavelength will exhibit at
its connection end the opposite of the other end of the cable, i.e. if
the remote end of the cable is open circuit then the connection end
will exhibit a short circuit. This can be useful in making a parallel
connected notch to tune out an interfering signal, such as paging or
whatever, and can be found empirically by snipping little bits off the
cable until it has most - or at least enough - effect.

By the same token if the remote end is short circuit then the
connection end will be seen as open circuit. This is often used
professionally in aerial combiner systems where the tuned feed
resonator - usually something like a metal beer barrel in
construction - has a short on its output pickup coil which, when
connected onto the cable that interconnects the barrels, looks like an
open circuit. Thus each barrel 'sees' none of the others on the system
just the aerial.

A piece of coax that is an even multiple of a quarter wavelength
reflects the same at the connection point as at the remote end. In the
example above of a combiner, the interconnect between the barrel
connection points is a half wavelength.

Hope that helps.

64. balun at resonance?

Newsgroup: rec.radio.amateur.antenna
Date: 2005-01-03 11:37:25 UTC
From: ml <m@di.net>
Message-ID: <m-7A1C85.06372003012005@news.verizon.net>
Source record: 84403

hi

i've build a 80 center fed dipole, cut for 80, to use multiband-- fed via coax.

my goal is to use a balun.

my recomendations so far have been for 1:1 /4:1 and 9:1, got nearly a equal tally of votes on each

leaves me a bit confused however

lets say i use a 9:1 for example

on 80 my dipole is resonant, therefore should be around 72ohms. lets presume it is

now w/a 9:1 attached what happens? is this my trade off, ie i become very ineff at resonance while gaining some better match at the non resonant points?

thanks

m

65. Plane of folded dipole?

Newsgroup: rec.radio.amateur.antenna

I will be attaching a 33' folded dipole for RX (made from 300 ohm twinlead) to the underside of my wood deck. It will be horizontal. Does it matter if the parallel conductors are in the horizontal or vertical plane?

If I just staple the twinlead to the joists (most convenient and invisible), the conductors will be in the horizontal plane.

try pumping a kw into a 6" ducky on 2m and see how long it takes to be a roast ducky... but it surely won't smell as good while cooking. oh, and since most ducky's are not very far from the people using them you may get a bit warm also.

>>>I forgot that
>>>15M wasn't a ham band when Lattin was >>>working on the patent for
this kluge.
>>>IIRC, the design was for 4, not 5, bands

Lattin (W4JRW) mentions in his December 1960 QST article that any of
his "decoupling stub" antennas that include 40 meters will also work
on 15 meters.

A quote from the article:

"Any of the antennas which will operate on 40M can also be used on 15M
as the 40M stubs will be approx. 3/4 wavelength long and will provide
decoupling."

ML wrote:
"Was wondering if there was anything that could be done (antenna feedline wise) to reduce chances of giving off interference from amy type of wire antennas."

Almost all medium wave broadcast stations reduce harmonic radiation by allowing only magnetic coupling to their radio towers. Capacitive coupling favors harmonics. The tower feedline is interrupted by a cpupling transformer which has a Faraday screen between its primary and secondary. Capacitive coupling is grounded out on the scree, Magnetic coupling is unaffected. Multiples of the fundamental frequency don`t get any boost from lower capacitive reactance at higher frequencies.

Too bad you couldn't use 300 ohm ladder line instead of coax. With the addition of a antenna tuner and ladder line, you could eliminate the use of the balun altogether and mathcing would not be a problem on any band (well almost).

```
+----------Z0--------Source
|
| 1/4WL stub
|
|
```

Given a constant Z0 above, there are no reflections at the connection point '+'. All the reflections occur at the open end of the stub. For an ideal lossless stub, the voltage to current ratio at the open-circuit reflection point is infinite. The voltage to current ratio at '+' is zero but there are no reflections occuring at '+'.

Think about it. If 100% reflection occured at the connection point, there would be no energy in the stub to be reflected at the open end. Yet measurements in the example above prove that the forward and reflected power inside the stub are identical to the forward and reflected power at the connection point.

It is not a good idea to use a coax-fed 80m CFD on the other bands because of losses due to SWR in the coax. Your balun problems are the least of your worries. If you feed the 80m CFD with ladder-line, you could use it on the other bands without suffering massive SWR losses. For that configuration, all one needs is a 1:1 choke at the tuner. Take a look at http://www.qsl.net/w5dxp/notuner.htm for some ideas on your antenna.

Permit me to ask a simple question. Aside from the transformation of
the impedance, what benefit were you planning to obtain from the
Balun? If you can't answer that question, then perhaps you don't
really need a Balun.

Another question, if you don't mind. Are you familiar with Choke
Baluns or the W2DU Balun?

I have been refused permission for any kind of outdoor Antenna due to the area in which I live in the UK having "permitted development rights removed"
I think that this may be a conservation area. Having recently passed the foundation course I am getting impatient - and dissapointed to say the least.
I am now faced with only one or two alternatives - an Indoor or Loft Antenna. I realise that this may restrict me to 2m only but at least it will be better than nothing - or to operate mobile only.
Has anyone on the group got any suggestions ? I have a fair sized loft with approx. 2.5m headroom, which runs the whole width of the house -almost 30ft. - is there anything I use in the loft like a loop Antenna for instance ? Or a fixed Station Antenna ?

Thaks for your help

Short answer: No

Think of it this way, what's the separation distance, relative to a
wavelength?
If it's less than 0.05 wavelength, then any difference is almost certainly
unobservable at any significant distance.

You won't be using metal staples though, right?

One would think that converting from a balanced antenna to unbalanced
feedline would be a primary benefit offered by a balun.

Dear John,

It has been my experience that the inefficiency of loft antennas make
them nearly useless. However, you have to work with what you've got.
My suggestion would be to build the best 20 meter dipole antenna you
can build for the space available. Try to keep the ends of the antenna
as far away from anything that absorbs RF as possible - even wood and
brick do absorb RF. If necessary, use loading coils in the dipole to
get the dipole resonant (at 14.070 MHz). Think about PSK31 as an
operational mode because that gives you the best bang for the buck in
terms of being heard 'round the world and being able to hear others in
adverse conditions.

I'm perfectly aware of most of the reasons for using a balun. I'm
trying to uncover the motivation of the complainant.

I really like to build things. I can weld even small material with a mig welder I have at home. You mentioned building a j pole. I thought of doing this myself. To be honest, I have always wanted to make something, (not necessarily an antenna) that I could sell for a few extra dollars on ebay or something. I wonder if a person could make any money building antennas and doing that? I am not wanting to get rich but I like building things and I could use some "pocket money". We just had our second shild born yesterday. It is my first son!

I thought about making a j-pole out of stainless steel tubing. It seems this would be attractive because of it being rustproof and to me more "visably appealing" that a copper one after it become tarnished. But some people have told me there is more resistance in stainless than copper. SOmeone else told me it would not amount to much in ham use.

Thought about building yagis too.

The only problem would be figuring out how to ship an antenna where it would not cost much.

Strioed wrote:
"Someone told me it would not amount to much in ham use."

It`s how long te elements need to be that determines the loss stainless steel adds to an antenna. For VHF, stainless is fine. For HF, you may be creating a combination antenna and dummy load by using stainless in place of aluminum or copper.

You can imitate what is usual commerciall practice for an amateur antenna at similar frequencies. There are gold-plated antennas, but this isn`t usual practice. It is extreme and certainly so for VHF. Some of the best antennas used at VHF have long been stainless steel. The big problem is stainless steel hardware which galls and binds. There is bound to be an anti-sieze preparation to mitigate this bind.

Best regards, Richard Harrison, KB5WZI

If all he wants is AM, and the ability to select 1 of 2 - possibly 3
CB channels, buy an old 23-ch xtal-based rig at a second-hand store
(Goodwill, ARC, Salvation Army, etc.) $10 - tops. Then, open the rig
and devise new mechanical stops on the rotary (channel) switch.

I did that for my Dad (the first W3DHJ) about 10 years ago. He was
in a nursing home and had lost his eyesight to the drugs he was taking
for COPD. .....anyways: I set up an old ICOM IC-22A for him to let
him use his local, favorite repeater and the 146.52 simplex freq.

The IC-22A is (was) basically built using the then-popular 23CH CB
'form factor'. What I did was "brute-force" solder some new stops on the
switch frame to only allow the thing to be switched between 2 selections
-- those two selections were then populated with the crystal pairs
for the repeater and the simplex freq. (Of course, in your case, you'd
select a pair [or triplet] of ajoining CB channels.)

That - plus a mag-mount antenna on the steel cover over the heat
radiator under the window - got my dad back On The Air.

There is a few possibilities except putting an antenna in the loft. I`ve read an article on the www amount tuning the rain gutter as an antenna. An other option is to just put up your antenna while transmitting. The antenna can be a telescopic 16' fishing rod with the antenna wire taped in the bottom of each joint. An adoption of this link http://pages.zdnet.com/radio_k7zb/id8.html

Make an STL and run it on NVIS by putting it horizontal abt 2' above the ground. http://www.qsl.net/aa5tb/loop.html

If you have a garden get a flagpole of glass fiber and run a wire inside the pole with an auto tuner by the base and fed by an underground coax (the other option is to feed it by a duplet coax and tuner inside).

If you goggle a bit on the net for "stelth antenna" you will probably find something suitable for your needs.

Regards

Geir

Subject:
Postal Lottery: Turn $6 into $60,000 in 90 days, GUARANTEED

Postal Lottery: Turn $6 into $60,000 in 90 days, GUARANTEED

I found this in a news group and decided to try it. A little while back, I was browsing through newsgroups, just like you are now and came across a message just like this that said you could make thousands of dollars within weeks with only an initial investment of $6.00!!!

So I thought yeah right, this must be a scam!!! But like most of us, I was curious, so I kept reading. Anyway, it said that you send $1.00 to each of the 6 names and addresses stated in the message. You then place your own name and address at the bottom of the list at #6 and post the message in at least 200 news groups. (There are thousands to choose from). No catch, that was it.

So after thinking it over, and talking to a few people first. I thought about trying it. I figured, what have I got to lose except 6 stamps and $6.00, right? So I invested the measly $6.00!!! Guess what? Within 7 days I started getting money in the mail!!! I was shocked!!! I figured it would end soon, but the money just kept coming in!!! In my first week, I had made about $25.00. By the end of the second week, I had made a total of over $1,000.00!!! In the third week, I had over $10,000.00 and it is still growing!!! This is now my fourth week and I have made a total of just over $42,000.00 and it is still coming in rapidly!!! It's certainly worth $6.00 and 6 stamps!!! I have spent more than that on the lottery!!!

Let me tell you how this works and most importantly, why it works!!!

Also, make sure you print a copy of this message now. So you can get the information off of it as you need it. I promise you that if you follow the directions exactly, that you will start making more money than you thought possible by doing something so easy!!!

Suggestion: Read this entire message carefully!!! (Print it out or download it.) Follow the simple directions and watch the money come in!!! It's easy!!! It's legal!!! Your investment is only $6.00 (plus postage).

IMPORTANT: This is not a rip-off!!! It is not illegal!!! ? It is almost entirely risk free and it really works!!! If all of the following instructions are adhered to, you will receive extraordinary dividends!!!

Please note: Follow these directions EXACTLY, and $60,000.00 or more can be yours in 20 to 90 days!!! This program remains successful because of the honesty and the integrity of the participants!!! Please continue its success by carefully adhering to the instructions.

You will now become part of the mail order business. In this business your product is not solid or tangible, it is a service. You are in the business of developing mailing lists. Many large corporations are happy to pay big bucks for quality lists. However, the money made from a mailing list is secondary to the income which is made from people like you and me asking to be included on your mailing list!!!

Here are the 4 easy steps to success:-

Step 1:- Get 6 separate pieces of paper and write the following on each piece of paper.

PLEASE PUT ME ON YOUR MAILING LIST

Now get 6 U.S. dollar bills and place ONE inside each of the 6 pieces of paper so the bills will not be seen through the envelopes (to prevent mail theft). Next, place one paper in each of the 6 envelopes and seal them, you should now have 6 sealed envelopes. Each with a piece of paper stating the above phrase, your name and address, and a $1.00 bill.

THIS IS ABSOLUTELY LEGAL!!! YOU ARE REQUESTING A LEGITIMATE SERVICE AND YOU ARE PAYING FOR IT!!!

Like most of us, I was a little skeptical and a little worried about the legal aspect of it all. So I checked it out with the U.S. Postal Service and they confirmed that it is indeed legal!!!

Mail the 6 envelopes to the following addresses:-

#1)Eric Stilley
1715 Possum Trail
Harker Heights, TX 76548

#2)Pierre Jenkins
7816 Regent Drive
Arlington, TX 76001

#3)P. Miller
41 Kenview Ave.
Kenmore, New York 14217

#4)Trish Smollett
35 Madison St
Fort Erie, Ontario L2A 3Z7

#5) Jack Genua
P.O. Box 1420
Crystal Beach, Ontario L0S 1B0

#6) Elizabeth Cooper
1003 S Fremont
Springfield Missouri 65804

Step 2:- Now take the #1 name off the list that you see above, move the other names up (6 becomes 5, 5 becomes 4, etc.) and add your name as number 6 on the list.

Step 3:- Change anything you need to, but try to keep this message as close to what you see as possible. Now, post your amended message to at least 200 news groups. I think there are close to 24,000 groups!!! All you need is 200, but remember, the more you post, the more money you make!!! This is perfectly legal!! If you have any doubts, refer to Title18 Sec. 1302 & 1341 of the postal lottery laws. Keep a copy of these steps for yourself and whenever you need money, you can use it again.

Please remember that this program remains successful because of the honesty and the integrity of the participants and by their carefully adhering to the directions!!!

Look at it this way. If you are of integrity, the program will continue and the money that so many others have received will come your way!!!

Note: - You may want to retain every name and address sent to you, either on your computer or hard copy and keep the notes people send you. This verifies that you are truly providing a service. Also, it might be a good Idea to wrap the $1 bills in dark paper to reduce the risk of mail theft.

So, as each post is downloaded and the directions carefully followed, six members will be reimbursed for their participation as a list developer with one dollar each. Your name will move up the list geometrically so that when your name reaches the #1 position, you will be receiving thousands of dollars in cash!!! What an opportunity for only $6.00!!! ($1.00 for each of the first six people listed above).

Send it now, add your own name to the list and your in business!!!

DIRECTIONS FOR HOW TO POST TO A NEWS GROUP!!!

Step 1:- You do not need to re-type this entire message to do your own posting. Simply put your cursor at the beginning of this message and drag your cursor to the bottom of this message and select copy from the edit menu. This will copy the entire message into the computer memory.

Step 2:- Open a blank note pad file and place your cursor at the top of the blank page. From the edit menu select paste. This will paste a copy of the message into notepad so that you can add your name to the list.

Step 3:- Save your new notepad file as a txt file. If you want to do your posting in a different setting, you'll always have this file to

go back to.

Step 4:- Use Netscape or Internet Explorer and try searching for various news groups (on-line forums, message boards, chat sites, discussions, etc.)

Step 5:- Visit these message boards and post this message as a new message by highlighting the text of this message from your notepad and selecting paste from the edit menu. Fill in the subject, this will be the header that everybody sees as they scroll through the list of postings in a particular group. Click the post message button. You've done your first one! Congratulations!!! All you have to do is jump to different news groups and post away, after you get the hang of it, it will take about 30 seconds for each news group!

REMEMBER, THE MORE NEWS GROUPS YOU POST IN, THE MORE MONEY YOU WILL MAKE!!! (But you have to post a minimum of 200).

That's it!!! You will begin receiving money from around the world within days!!! You may eventually want to rent a P.O. Box due to the large amount of mail you will receive. If you wish to stay anonymous, you can invent a name to use, as long as the postman will deliver it.

JUST MAKE SURE ALL THE ADDRESSES ARE CORRECT!!!

Now the why part. Out of 200 postings, say you receive only 5 replies (a very low example). So then you made $5.00 with your name at #6 on the letter. Now, each of the 5 persons who sent you $1.00 make the minimum 200 postings, each with your name at #5 and only 5 persons respond to each of the original 5, that is another $25.00 for you. Now those 25 each make 200 MINIMUM posts with your name at #4 and only 5 replies each, you will bring in an additional $125.00!!! Now, those 125 persons turn around and post the minimum 200 with your name at #3 and only receive 5 replies each, you will make an additional $625.00!!! OK, now here is the fun part, each of those 625 persons post a minimum 200 messages with your name at #2 and they each only receive 5 replies, that
just made you $3,125.00!!! Those 3,125 persons will all deliver this message to 200 news groups. If just 5 more reply you will receive $15,625.00!!! All with an original investment of only $6.00!!! Amazing isn't it!!!! When your name is no longer on the list, you just take the latest posting in the news groups and send out another $6.00 to the names on the list, putting your name at number 6 again.

You must realize that thousands of people all over the world are joining the internet and reading these messages every day!!! Just like you are now!!! So, can you afford $6.00 and see if it really works? I'm glad I did!!! People have said, "what if the plan is played out and no one sends you the money?" So what!!! What are the chances of that happening, when there are tons of new honest users and new honest people who are joining the internet and news groups everyday and are willing to give it a try? Estimates are at 20,000 to 50,000 new users,

every day!!!

REMEMBER PLAY HONESTLY AND FAIRLY AND THIS WILL REALLY WORK!!!

-- Comments/Feedback (please post your feedback/experiences here) --

Not bad for 1 hr's work..made me around $5320 in roughly 35 days
Anthony M - TX

Hello, I rcvd 269 bucks in the post in 2 weeks.
Dan Miami - FL

I had to wait around 10 days before I had any results - $13,450 as of 3rd Jan 2003 to date (14th Feb 2003).Am gonna re-post it again for more money!!
Del from Alberta - Canada

Only received around £588 in the post the last 2 months since I started the program but I'd posted to approx. 100 newsgroups.
James P - Manchester, UK

Cool..didn't expect much out of this "scam" initially but I have pay my credit card bill
Mustafa - Jordan

For $6,I made $246 in 2 weeks
ROMEO2326 - Little Rock, AR -US of A

Hey, just droppin a line to say that after posting to well over 820 newsgroups on google and my ISP newsgroup server over a period of 4 1/2 months ,Ive raked in $54280 . Mucho dinero baby!!!! Peace..
Drew Dallas - TX

John,
If you string a wire antenna outside, can they do anything to you other than
have you take it down? Some people in your position have gotten away with
it. You could also put a 20 m vertical inside a plastic pipe, and call it a
flagpole; radials might get a little touchy.

I would suggest that you get someone to calculate the antenna with NEC or similar to get the right lengths and resistive loss. Then build an prototype for 2m and 70cm and put it on eBay to check if there is any interest for the antenna. To reduce the size it might be an idea to think about using Parker tube fittings in some of the joints.

Ken,
I swept a pair of 300:75 Ohm TV baluns back/back on an HP network analyzer
once. As I recall, they were useless below about 7 MHz.

Uhhhhhh. Was gonna.

ARRL tech dep't once told me that I could use metal staples on 1000
watt, 450 ohm ladderline. Figured this was the same thing. How much
coupling can a skinny, short staple every 32" inject on a 33 ft RX
antenna?

What are my options, other than staples or those old twinlead
standoffs?

Dear Rick, N6RK:

If you believe that none of the "other" analyzers will work at your site
because of the presence of strong signals from below 1700 kHz, then you
could do one of the following:

1. You could build a high-pass filter to go between analyzer and antenna
to attenuate the MF signals. I have heard of people doing this successfully
such that the filter is essentially transparent at HF.

2. You could add one or more band stop resonators that can be tuned to
number 1 and really cut down the one or two most strong broadcast signals.

3. You could search for a used or new bridge type of instrument. They
tend to be insensitive to off-frequency signals.

4. Many types of antennas will deliver little of a signal that is far
away in frequency. An inverted L is expected to deliver a lot of signal
from nearby MF stations. A balanced LPDA with a shorting strap at its far
end is expected to pick up little from vertically polarized MF stations.

Let the group know what type of antennas you wish to analyze.

Stainless steel causes significant loss only if the antenna is long and small in diameter, such as an HF antenna (particularly one for the lower frequency bands) made from stainless steel wire, or if the antenna is electrically very small, such as a small tuned HF loop.

Your antenna isn't in either of those categories, so the stainless won't cause any appreciable loss.

I really appreciate the advice! What is "NEC"? I assume it is an
antenna performance computer program?

Are you saying build a dual band prototype of one for each band?

What are "Parker tube fittings"?

John,

The most power-efficient antenna which will fit into a loft is the so-called magnetic loop.

A loop, 2 or 2.5-metres square, or a circular or broad rectangular loop of the same perimeter, made with 25mm plumbers' copper pipe will work reasonably well at frequencies as low as the 160m band.

The greater the area enclosed by the loop and the greater the conductor diameter, the greater the efficiency.

A remotely-controlled, slow-motion, vacuum tuning capacitor (1000pF for 160m) can be expensive. But capacitors rapidly get progressively much smaller on the 80 and 40m bands, etc. A range of three bands, eg., 80, 40 and 20m, can be covered with one capacitor.

Very high efficiency, comparable with a 1/2-wave dipole can be acheived at the higher frequencies within a much smaller space.

Whether you make one or purchase one, or just amuse yourself with figures you can compare performance versus dimensions by downloading program MAGLOOP4 from website below. Download in a few seconds and run immediately.

Subject:
Postal Lottery: Turn $6 into $60,000 in 90 days, GUARANTEED

Postal Lottery: Turn $6 into $60,000 in 90 days, GUARANTEED

I found this in a news group and decided to try it. A little while back, I was browsing through newsgroups, just like you are now and came across a message just like this that said you could make thousands of dollars within weeks with only an initial investment of $6.00!!!

So I thought yeah right, this must be a scam!!! But like most of us, I was curious, so I kept reading. Anyway, it said that you send $1.00 to each of the 6 names and addresses stated in the message. You then place your own name and address at the bottom of the list at #6 and post the message in at least 200 news groups. (There are thousands to choose from). No catch, that was it.

So after thinking it over, and talking to a few people first. I thought about trying it. I figured, what have I got to lose except 6 stamps and $6.00, right? So I invested the measly $6.00!!! Guess what? Within 7 days I started getting money in the mail!!! I was shocked!!! I figured it would end soon, but the money just kept coming in!!! In my first week, I had made about $25.00. By the end of the second week, I had made a total of over $1,000.00!!! In the third week, I had over $10,000.00 and it is still growing!!! This is now my fourth week and I have made a total of just over $42,000.00 and it is still coming in rapidly!!! It's certainly worth $6.00 and 6 stamps!!! I have spent more than that on the lottery!!!

Let me tell you how this works and most importantly, why it works!!!

Also, make sure you print a copy of this message now. So you can get the information off of it as you need it. I promise you that if you follow the directions exactly, that you will start making more money than you thought possible by doing something so easy!!!

Suggestion: Read this entire message carefully!!! (Print it out or download it.) Follow the simple directions and watch the money come in!!! It's easy!!! It's legal!!! Your investment is only $6.00 (plus postage).

IMPORTANT: This is not a rip-off!!! It is not illegal!!! ? It is almost entirely risk free and it really works!!! If all of the following instructions are adhered to, you will receive extraordinary dividends!!!

Please note: Follow these directions EXACTLY, and $60,000.00 or more can be yours in 20 to 90 days!!! This program remains successful because of the honesty and the integrity of the participants!!! Please continue its success by carefully adhering to the instructions.

You will now become part of the mail order business. In this business your product is not solid or tangible, it is a service. You are in the business of developing mailing lists. Many large corporations are happy to pay big bucks for quality lists. However, the money made from a mailing list is secondary to the income which is made from people like you and me asking to be included on your mailing list!!!

Here are the 4 easy steps to success:-

Step 1:- Get 6 separate pieces of paper and write the following on each piece of paper.

PLEASE PUT ME ON YOUR MAILING LIST

Now get 6 U.S. dollar bills and place ONE inside each of the 6 pieces of paper so the bills will not be seen through the envelopes (to prevent mail theft). Next, place one paper in each of the 6 envelopes and seal them, you should now have 6 sealed envelopes. Each with a piece of paper stating the above phrase, your name and address, and a $1.00 bill.

THIS IS ABSOLUTELY LEGAL!!! YOU ARE REQUESTING A LEGITIMATE SERVICE AND YOU ARE PAYING FOR IT!!!

Like most of us, I was a little skeptical and a little worried about the legal aspect of it all. So I checked it out with the U.S. Postal Service and they confirmed that it is indeed legal!!!

Mail the 6 envelopes to the following addresses:-

#1)Eric Stilley
1715 Possum Trail
Harker Heights, TX 76548

#2)Pierre Jenkins
7816 Regent Drive
Arlington, TX 76001

#3)P. Miller
41 Kenview Ave.
Kenmore, New York 14217

#4)Trish Smollett
35 Madison St
Fort Erie, Ontario L2A 3Z7

#5) Jack Genua
P.O. Box 1420
Crystal Beach, Ontario L0S 1B0

#6) Elizabeth Cooper
1003 S Fremont
Springfield Missouri 65804

Step 2:- Now take the #1 name off the list that you see above, move the other names up (6 becomes 5, 5 becomes 4, etc.) and add your name as number 6 on the list.

Step 3:- Change anything you need to, but try to keep this message as close to what you see as possible. Now, post your amended message to at least 200 news groups. I think there are close to 24,000 groups!!! All you need is 200, but remember, the more you post, the more money you make!!! This is perfectly legal!! If you have any doubts, refer to Title18 Sec. 1302 & 1341 of the postal lottery laws. Keep a copy of these steps for yourself and whenever you need money, you can use it again.

Please remember that this program remains successful because of the honesty and the integrity of the participants and by their carefully adhering to the directions!!!

Look at it this way. If you are of integrity, the program will continue and the money that so many others have received will come your way!!!

Note: - You may want to retain every name and address sent to you, either on your computer or hard copy and keep the notes people send you. This verifies that you are truly providing a service. Also, it might be a good Idea to wrap the $1 bills in dark paper to reduce the risk of mail theft.

So, as each post is downloaded and the directions carefully followed, six members will be reimbursed for their participation as a list developer with one dollar each. Your name will move up the list geometrically so that when your name reaches the #1 position, you will be receiving thousands of dollars in cash!!! What an opportunity for only $6.00!!! ($1.00 for each of the first six people listed above).

Send it now, add your own name to the list and your in business!!!

DIRECTIONS FOR HOW TO POST TO A NEWS GROUP!!!

Step 1:- You do not need to re-type this entire message to do your own posting. Simply put your cursor at the beginning of this message and drag your cursor to the bottom of this message and select copy from the edit menu. This will copy the entire message into the computer memory.

Step 2:- Open a blank note pad file and place your cursor at the top of the blank page. From the edit menu select paste. This will paste a copy of the message into notepad so that you can add your name to the list.

Step 3:- Save your new notepad file as a txt file. If you want to do your posting in a different setting, you'll always have this file to

go back to.

Step 4:- Use Netscape or Internet Explorer and try searching for various news groups (on-line forums, message boards, chat sites, discussions, etc.)

Step 5:- Visit these message boards and post this message as a new message by highlighting the text of this message from your notepad and selecting paste from the edit menu. Fill in the subject, this will be the header that everybody sees as they scroll through the list of postings in a particular group. Click the post message button. You've done your first one! Congratulations!!! All you have to do is jump to different news groups and post away, after you get the hang of it, it will take about 30 seconds for each news group!

REMEMBER, THE MORE NEWS GROUPS YOU POST IN, THE MORE MONEY YOU WILL MAKE!!! (But you have to post a minimum of 200).

That's it!!! You will begin receiving money from around the world within days!!! You may eventually want to rent a P.O. Box due to the large amount of mail you will receive. If you wish to stay anonymous, you can invent a name to use, as long as the postman will deliver it.

JUST MAKE SURE ALL THE ADDRESSES ARE CORRECT!!!

Now the why part. Out of 200 postings, say you receive only 5 replies (a very low example). So then you made $5.00 with your name at #6 on the letter. Now, each of the 5 persons who sent you $1.00 make the minimum 200 postings, each with your name at #5 and only 5 persons respond to each of the original 5, that is another $25.00 for you. Now those 25 each make 200 MINIMUM posts with your name at #4 and only 5 replies each, you will bring in an additional $125.00!!! Now, those 125 persons turn around and post the minimum 200 with your name at #3 and only receive 5 replies each, you will make an additional $625.00!!! OK, now here is the fun part, each of those 625 persons post a minimum 200 messages with your name at #2 and they each only receive 5 replies, that
just made you $3,125.00!!! Those 3,125 persons will all deliver this message to 200 news groups. If just 5 more reply you will receive $15,625.00!!! All with an original investment of only $6.00!!! Amazing isn't it!!!! When your name is no longer on the list, you just take the latest posting in the news groups and send out another $6.00 to the names on the list, putting your name at number 6 again.

You must realize that thousands of people all over the world are joining the internet and reading these messages every day!!! Just like you are now!!! So, can you afford $6.00 and see if it really works? I'm glad I did!!! People have said, "what if the plan is played out and no one sends you the money?" So what!!! What are the chances of that happening, when there are tons of new honest users and new honest people who are joining the internet and news groups everyday and are willing to give it a try? Estimates are at 20,000 to 50,000 new users,

every day!!!

REMEMBER PLAY HONESTLY AND FAIRLY AND THIS WILL REALLY WORK!!!

-- Comments/Feedback (please post your feedback/experiences here) --

Not bad for 1 hr's work..made me around $5320 in roughly 35 days
Anthony M - TX

Hello, I rcvd 269 bucks in the post in 2 weeks.
Dan Miami - FL

I had to wait around 10 days before I had any results - $13,450 as of 3rd Jan 2003 to date (14th Feb 2003).Am gonna re-post it again for more money!!
Del from Alberta - Canada

Only received around £588 in the post the last 2 months since I started the program but I'd posted to approx. 100 newsgroups.
James P - Manchester, UK

Cool..didn't expect much out of this "scam" initially but I have pay my credit card bill
Mustafa - Jordan

For $6,I made $246 in 2 weeks
ROMEO2326 - Little Rock, AR -US of A

Hey, just droppin a line to say that after posting to well over 820 newsgroups on google and my ISP newsgroup server over a period of 4 1/2 months ,Ive raked in $54280 . Mucho dinero baby!!!! Peace..

>Isnt it a copywrite problem if you copy someone else's antenna design?

Hi OM,

We used to have a PhD here who would have claimed so (after having claimed the Earth, Sea, and the Sky in patents "pending"). As a girl friend of mine described "he had all of his sense educated out of him."

Copyright covers claims to authorship and trade of the author's product - which in this case the only tangible evidence is generally found on paper in written or drawn form or in other means of recording.

Patent covers claims to invention and trade of the inventor's product - which in this case would be that antenna.

In either case, the law provides the author or inventor a means to pursue his loss of profit if these works are duplicated without license or permission. With few exceptions, Common Law would suggest that the practice of duplication by an individual for their own use (and not to produce for sale or distribution) is allowed. Copyright and Patent are then issues of the marketplace, not the home.

Patents expire in time. Copyright expires after the author does (and only many years after that). Both then enter into the Public Domain.

As far as legal advice goes, caveat reader. As I pointed out above, the law provides a means, the courts, not a guarantee. Further, it should come as no surprise that even lacking this, you can always be taken to court - even if you don't get out of bed for fear of being sued.

Rick, you don't HAVE to use a laptop, or carry it to the antenna or worry about being able to see the LCD. Simply take your N2PK, couple it to the feedline in the shack, (and your desktop computer) do the OSL calibration out at the antenna end of the feedline and measure the antenna from the comfort of your operating position. You've just calibrated out the feedline. You can REALLY use the VNA.

Hi OM,

For all intents and practical purposes, your Ohmmeter is barely a continuity tester and wholly useless in forecasting RF resistance if the material is unknown.

There are very few retail Ohmmeters that are very accurate below 10 Ohms and clearly inadequate below 1 Ohm. The proper instrument would use what are called "Kelvin clips," which are simply the leads to a Kelvin Bridge. This is a four terminal measurement and it makes heavy demands on a current source and requires a good shunt to insure decent resolution and accuracy.

Unless you are building a small loop and need to confirm contact and joint resistance, you will probably never need one. Wire tables provide enough information that is accurate.

Years ago there was a very interesting letter from a real old timer who put a telephone element across the output of his transmitter .. He was having a voice QSO with another ham for the first time.. He does not remember what happened but woke up on the floor. The RF had caused some intercranial changes and this fellow was fortunate enough to make it alive. I remember years ago giving SW diathermy transcranial for Alzheimer's with capacity plates at either ear. I would not want to do that again but it was standard practice. It is really amazing what tissue heating feels like with those RF fields ..... adds a new meaning to the phrase ..."a warm feeling within".

Yes NEC is a antenna calculation program.
Try the Parker website and you will find the fittings I'm thinking about (
there is a similar type called swage lock)

Here is an example of an dual band j-pole
http://www.durm-online.de/jpole.htm
I have seen several variations of this design, but can't find any of the
links.

I have run into this situation twice.

Once I installed a multiband - parallel wire - dipole for 10, 15, 20 and
40m and had reasonably good results.

The other place I installed a "Slinky dipole" which worked quite well on
10, 15, 20 and 40; but was marginal on 80m. Also had the disadvantage
that I had to go up to change bands.

Friends facing the same situation have used wire loop around the outside
of the house, and a hinged vertical which lay behind a fence and only
came up after dark.

Good luck
Dave

> Would there be a problem using stainless steel elements in a beam
> antenna? Can I solder the lead in to stainless?

Hi:
There are some problems with using stainless steel for elements in a beam.
1) Stainless Steel has much higher loss than aluminum. Remember because of skin effect the RF current flows only in the outer few thousand of an inch of the metal. The depth of conduction gets less as the frequency goes higher so 2m antenna made of stainless would have higher loss than a 6m and 440 antenna would have even more.
2) Stainless Steel is heavy. It means that the antenna would need to be heavily constructed just to hold up it's own weight.
3) Stainless Steel can be soldered to but not easily. So can aluminum be soldered but soldering is not the best way to make connections to antennas even ones made out of copper as the solder doesn't hold up well in the weather.
Of course there are some antennas that are made of stainless steel because they need the corrosion resistance or the strength and flexibility of stainless steel. Mobile whips come to mind for one case, the other would be an antenna that is used in a corrosive environment like on a buoy at sea.
Of course if you need a antenna made out of a strong light weight corrosion resistant metal, I know of one that's made from titanium. It's as strong as steel, almost as light as aluminum and is a good conductor but it's very costly compared to aluminum.

Hi John,

I had a similar problem and initially tried a Buddipole dipole in the
attic. It worked but not too well and also flooded the house with RFI.
I then switched to a screwdriver antenna hidden in a rubbermaid shed
and it works fine. See: http://www.qrz.com/w4tqt

>Patent covers claims to invention and trade of the inventor's product
>- which in this case would be that antenna.

Right. And, the invention claimed must be novel (new), useful, and non-obvious to a skilled practitioner of the art. In theory, it has to actually work (otherwise it isn't "useful") but in most cases the Patent Office seems to have stopped requiring any sort of actual evidence on this point.

Antenna designs which were originally published decades ago (and that seems to be most of them) cannot now be patented. Neither, in principle, can slight or trivial or obvious variations on older antennas.

>In either case, the law provides the author or inventor a means to
>pursue his loss of profit if these works are duplicated without
>license or permission. With few exceptions, Common Law would suggest
>that the practice of duplication by an individual for their own use
>(and not to produce for sale or distribution) is allowed.

My understanding is that this is true to some extent for copyright (the "fair use" principle). I've been told that it is _not_ true for patented inventions. You're allowed to re-create the patented invention yourself in order to study it, or to figure out a different way of achieving the same goal (that is, a similar device which doesn't actually infringe on the patent). However, re-creating the patented invention for actual personal use is not allowed.

In practice, of course, this usually goes undetected and nobody gives a hoot. Some patentholders have a practice of offering anyone who asks a license to manufacture one (or a few) of the devices, for their own use, with no royalty fee... but patentholders are _not_ required to do so, or to license the patent to anyone at all.

Some years ago, the Bose corporation earned itself some bad blood in the audiophile community, by sending a stern letter to Speaker Builder magazine stating that a homebrew speaker-building article published therein used a design which Bose felt infringed on one of their patents (a "birdhouse" multi-chamber resonator design, I believe). They accused Speaker Builder of "contributory infringement" of the patent (i.e. encouraging others to infringe). This action was viewed by many of the magazine's readers as an example of a big, monied corporation bullying individuals.

>As far as legal advice goes, caveat reader. As I pointed out above,

If you do the actual calculations, you'll find that even the greater loss of stainless is insignificant for typical VHF and higher frequency antennas, even when made with wire of moderate diameter. When made with tubing, loss is even less.

And, it's not necessarily true that antenna loss increases with frequency. The skin depth decreases only as the square root of frequency, while for a given antenna length in wavelengths, the element length is inversely proportional to frequency. For example, if you increase the frequency by a factor of two, the skin depth decreases by a factor of about 1.4 while the length shortens by a factor of 2. The net result is *lower* total resistance as the frequency increases -- a factor of about 0.71 each time you double the frequency. (This is assuming that you maintain the same absolute conductor diameter and keep the length constant in terms of wavelength.) That's why stainless steel isn't a problem for higher frequency antennas.

John- must second Reg- for an antenna for 20-10 meters. AEA used to make
such an antenna (cant remember the name, but think now made by MFJ. As
to higher freqs (dont laugh too hard) a friend, in K.Falls, OREGON
lived in an apartment with a loft - placed a rotator up in it, with a
combination 3 element 2 meter quad, nested inside a 2 element 6 meter
quad. One caviat, tho, make sure that if it is insulated (the loft),
that no alumiuium foil is on it for a vapor barrier! (makes a great
faraday shield!) Such an antenna is indeed worthy, as he worked ZL/VK,
as well as the east coast during f2, as well as multihop openings on
Eskip! one other thing to consider is , if you have ground fault
outlets, they are suceptable to RF tripping them, as many have found
out! As info-- Jim NN7K

>Like a R5 or beam.

If you have access to the catalogs, antenna specs or even the advertisements from HyGain, you can see stubs all over their verticals.

As to its real purpose. It is often, but not exclusively a means of imposing the equivalent of an open circuit in a part of the antenna, so as to make the antenna seem shorter at that frequency.

In other applications a stub is just a way of inserting a capacitance or an inductance into the feedline. The inductance or capacitance obtained in this way is generally cheaper and less vulnerable to the elements than using a discrete component.

As to how it does it - it is the nature of a section of transmission line (stub) to transform any non-matching impedance at one end into a different impedance seen looking into the other end. In the particular case of a stub the terminating impedance is usually a short or an open, thus reflecting a pure reactance to the other end. If you want more detail than that, then it's time to start looking into an understanding of the transmission line equations.

That is exactly why I asked. Since you do not want RF on the outer shield, then instead of a transformer type balun, you may find that the choke balun or W2DU balun will better serve your needs. It is designed specifically to reduce the flow of RF on the outer shield.
>

>
> i am still missing the info i seek

You were apparently disturbed by my question. However, it has been my experience that it is very important to find out what is the real problem, because it is only when you know the real problem you can hope to find the best answer.

For example, someone asks for a recommendation for a good hammer, and he gets hundreds of recommendations for good hammers - all different and all good hammers for something, but none are the best answer for his needs. Once it is discovered that what he really needs is a good way to kill chickens - then we tell him to wring their necks.

Do you see my point?

It is truly a shame, but most people do not know how to seek help, properly. They must forget their idea of a solution and define their real problem. It is not a natural talent, but is certainly a valuable one, which earns them better answers, quicker.

The filter needs to have no group delay in the band of measurement (not
just flat group delay and amplitude). It is impossible to build a high
pass filter with no group delay.

I have a 90 foot vertical for 160 meters. I use it because it gets
out very well. Unfortunately, it is also a good BCB receive
antenna, developing nearly a volt of RF.

Source record: 84364

I have a 136' (1/2 wave on 80m) Carolina Windom from Radio Works. It's a good antenna, and works well for me.

There is a transformer or balun at the feedpoint (14% off center). Then, a 22' coax downdrop to a choke balun. Coax on to the shack.

What function does the choke balun play? There's coax on both sides of it. I thought unbalanced signal goes in one end of a choke balun, and balanced signal comes out. Having coax on the balanced output side of the balun would seem to be counterproductive. But, it works, and works well. How/why?

Does the off-center feed shift the current peak over by the amount of offset on some bands? Is the current peak symmetrically centered on some bands? What is the effect of off center feed?

The antenna is rated for 160m use, too. What do I have when on 160? Is it sort of a 22' top loaded vertical? It's a shortie, physically, for 160, if you consider only the horizontal part. Likely very reactive---which is why power input rating on 160 is only 500 watts.

Jack Painter wrote:
"Modelimg examples cited below appear to be incorrect for lightning, similar to how modeling for ocean weaves cannot be done in a bathtub,---."

As far as I know there is one set of rules which rules electrical phenomena, not rules for weak snd onother set of rules for strong electricity. Lightning is so stromg that it sometimes seems to play by its own rules, but it really does not.

Jack`s waves in a bathtub metaphor was particularly ironnic. Franklin`s experiments proved the electricity he was studying was the same stuff on whatever scale. He charged Leyden jars from the clouds then used the stored charge to conduct other experiments with the stored charge as his contempories were doing. Franklin found that hemp twine was a conductor of sorts while silk was an insulator.

Irony springs from Jacj`s bathtub metaphor. According to the December 2001 issue of "Modern Maturity":
"Alexander Graham Bell - yes, of telephone fame - also invented the hydrofoil, a boat that rides on a duchion of air. He tested models of this invention in his tub."

Best regards, Richard Harrison, KB5WZI

Any impedance/network analyser is going to need a BCB-reject filter in order to handle that level of interference. However, imperfections in the filter don't matter with a more advanced VNA such as the N2PK design, because the filter can be included *inside* the calibration loop.

As Harold W4ZCB says, a long coax can be included inside the calibration loop as well, so you could make the measurements from home... in principle. But you'd have to do a lot of shuttling back and forth between the shack and the antenna to swap connectors, start the VNA etc. At Rick's QTH (www.n6rk.com) that would involve a *lot* of travelling time.

Seriously, Rick, if the lack of a laptop is all that's stopping you... then get a laptop already! (Almost any old wreck will run an N2PK VNA.) Add an awning, a camping table, chair and cooler, and you're all set for accurate impedance measurements in the field.

I'm going to be doing a lot of that in the next two years, but the environmental problems will be slightly different. Where can I find a laptop with a screen demister and two-speed wipers?

Hello,

Throw as much wire as you can up in your loft, feed it in the center with ladder line to a tuner. I used one for years. I called it a "Dog-eared dipole" because I let the ends just droop down and along the attic floor when I ran out of attic length. It was cut for 40 meters (33 feet per side) and worked good enough. Since it's a balanced load, I don't have any trouble with TVI, but it does get into the telephone sometimes. I just used a staple gun to get it as high as I could.

Good luck & 73's

Lots of good advice elsewhere in the thread. You certainly can operate HF from a loft that size... though RF interference may be a problem.

But we're getting ahead of ourselves - it's too soon to give up on outside antennas yet.

No matter where you are, the planners don't have the authority to issue a blanket refusal. Even in a conservation area, there are still plenty of legitimate options involving 'stealth' antennas, night-time operation etc.

Here in town, there's an amateur who lives in a Listed building that is right opposite the District Council offices - the planning officer's desk is by the window, literally overlooking the rear of his house! It's hard to imagine a worse situation than that, yet he *can* put up outside antennas, and he gets out fine on 80m and VHF.

So don't ever accept a flat "No" for an answer. Push back at officialdom. Find out if you really are in a conservation area, and by what right they are restricting you. Ask them for chapter-and-verse on that. On the technical side, think up some solutions for outdoor antennas that they cannot reasonably refuse. Keep pushing - politely, but also relentlessly. When they eventually realise that you're not going to give up, they *will* say "Yes" to something.

Talk to the RSGB Planning Panel (details at www.rsgb.org) and I'm sure they can help you.

135. Center Fed " Zepp " with Coaxial Balun ?

Newsgroup: rec.radio.amateur.antenna
Date: 2005-01-04 11:35:12 UTC
From: Gary
Message-ID: <suukt0djpje0pbtorpounl0tkr3n3590qd@4ax.com>
Source record: 84274

I'm mulling over different antenna designs for this spring / summer
and a friend of mine has suggested for 80m on up a full size 80 meter
"dipole" 66' X inches per leg, center fed with 300 Ohm twinlead. He
has this arrangement and the twinlead comes into his house and is
connected to two 10' sections of RG-8X both rolled into a coil about
6" in diameter. He then takes and connects the braid and shield of one
of the coax coils to one leg of the twindlead and I'm not exactly
certain how the other leg is connected. He claims it's a 4:1 coaxial
balun. I wonder if some of the experts here are familiar with this
type of arrangement. He claims it has lower losses than connecting it
to the 4:1 balun in his tuner. Any thoughts on the subject ?

Thanks in advance

> loop.

GM Ian, Actually, I have used the N2PK under the same conditions that Rick has and you DON'T need the reject filter. That volt is an aggregate number and at any 2-3 Hz bandwidth that the VNA detector is looking at, it's at the uVolt level and not a bother. (Unless you tune TO the BC signal itself of course!) As for the walk, would probably do most of us some good, but I even substituted the guy that wanted the measurements made and a pair of $5. FRS radios for the walk. Works fine if you really want to measure the antenna. Rick can put the feedline, his transformers and the kitchen sink inside the cal loop and still measure his antenna if he REALLY wanted to use it.

Used Laptops with a parallel port (And worn out battery) are running 25-50 bucks around here. Had one given to me that Alice plays the cardgame with using the charger. Most will still hold a charge for an hour or so.

Dear Rick:
OK. Your vertical antenna certainly picks up a lot of stray RF.

However, one of the beauties of using a network analyzer is the ability to characterize the transmission line (even 1000 feet of it) and a filter that is between the network analyzer and the antenna, AND THEN to have the effects of all of the stuff between the analyzer and antenna removed so as to leave the properties of the antenna.

One has to measure the "stuff" (transmission line +) with the "stuff" disconnected from the antenna. Even if you went out to the antenna, you would need (temporarily) to disconnect the "stuff" from the antenna.

This scheme really works. One has some front-end-load required in order to characterize the "stuff," but then it is straight forward.

Well, if you like to build things and are thinking about something along the lines of a J-Pole, I have something that I have made about 50 of for my friends who just love having them.

It's a self-standing full sized J-Pole that fits into your pocket or backpack and does NOT need to be hung from something like the wire ribbon version.

Construction is simple, but does require welding as the unit is made from arced spring steel and 1/2 of an 8 ounce paint can.

The antenna and coax fit inside the can, which doubled as the Horizontal member of a J-Pole.

I purposely used a specially manufactured 4 ounce can suited for this purpose, with an opening tab (like on the old tobacco cans), that the lid itself became the horizontal member and would fit snugly to the bottom of the can for extra weight and support.

But the elements themselves are simple to come by. On 440 antenna's I used 3/4 inch tape measure spring steel and on 2-meter antenna's I used 1 inch tape measure spring steel.
You can buy tape measures or order the painted or unpainted steel in rolls from a supplier.

These are welded to the removable lid so that they roll inward and fit into the can when not in use.

To use the antenna, you affix the lid to the base and unroll the vertical and stub completely. They will stay open by themselves.

I also added 4 little arms about 2 inches long each on later antennas, that could be opened from the lid to give a larger 6 inch wide footprint to keep it from toppling over on the picnic table if it was a little windy to stay upright by itself.

It was a fun project, and everyone that got one put them to good use, especially on Field Day and Fox Hunts.

==========

Dear m, Confusion is only to be expected.

Its sometimes a good idea to take the average of the recommendations offered in this newsgroup.

But in your case you should include in the offerings a 0-to-0 balun - ie., no balun ar all.

So the most logical thing to begin with is NO balun (because it is the least expensive) which in all likelihood will probably do fine on 80 meters using a coax feedline.

But, having an experimental mind, after that you could try an indeteminate impedance-to-indeterminate impedance choke balun. The sort wound with twin speaker cable on a ferrite ring. Which in some circumstances MIGHT work slightly better by doing what a balun is supposed to do but will certainly not make things worse.

And whatever you use, a tuner will be essential for multi-band operation. Length of dipole is non-critical, whatever fits into your backyard. Prefer 450-ohm or open-wire transmission line for the best performing HF dipole antenna you will ever have. Unless you can make it even higher.

Happy experimenting in 2005 !

It's not surprising a balun intended for TV frequencies doesn't work at all on MF and LF.

The inductance of the balun windings is far too small. Like-wise, the ferrite core dimensions and the number of turns. The windings are practically short-circuits.

I wonder if the isolator simply reflects the common mode waves
thus causing common mode standing waves on the vertical section?

The law does *forbid* you from making a patented item even for your own use. (From http://www.uspto.gov/web/offices/pac/doc/general/index.html#patent: "The right conferred by the patent grant is, in the language of the statute and of the grant itself, ï¿½the right to exclude others from making, using, offering for sale, or sellingï¿½ the invention in the United States or ï¿½importingï¿½ the invention into the United States." Notice the word "making".)

But the law doesn't *prevent* anyone from doing anything they like, as long as they're not caught. This general attitude is also common among people who pirate software, music, and other copyrighted items, as well.

I live in a no antenna HOA area. I ended up laying a #22 wire around the outer edge of my roof and hooked it up as a loop. It is a random length of over 200' and varies in height from 7' to 20'. I chose the wire color to match the red tile roof so that you can't see it. I use it on 160 through 10 and have had decent results, nothing spectacular, but generally good solid contacts. (I usually run 50 watts, although sometimes less.) Just another idea for you to consider...

150. ELF/VLF/LF/BCB ferrite bar antenna?

Message-ID: <a22mt0p19ickcievc59nsfs8fc6romt1gl@4ax.com>
Source record: 84288

Having modded my Ten Tec RX-320 for VLF/LF (for no good reason other than I was in there anyway), I am looking for a cheap and easy low low band antenna. Two miles of wire is not practical for my QTH. Also, big loops are problematic. So I am considering antennas using huge ferrite bars and reasonable wire lengths.

In particular, I am interested in the antenna entiled "Shortwave / AM / Longwave Radio Booster" shown at:
http://www.stormwise.com/vfr12cproject.htm

I would use the direct connect option, since my radio has no internal ferrite bar for coupling to.

(1) Does this make any sense at all?

I would put the turns on a bigger pipe and slide the ferrite into the bigger pipe. I am told that you can "fine tune" by sliding the ferrite bar. I am not sure what is being fine tuned, except maybe the inductance to get resonance with whatever cap is in the circuit.

If it does make sense, can I get this to work from 10kHz to 550kHz? 10kHz to 1500 kHz?

The vendor thinks so, but he is selling ferrite bars -- the bigger the better. He is recommending the 24" monster, with 300 turns and a 1 uF cap. However, using 27 ga magnet wire, I only need 5" to get 300 turns.

(2) Which ferrite bar should I use -- 12", 24" or 36" -- to get the result I need without overkill? See table at:
http://www.stormwise.com/vlf.htm

(3) Is there somthing I can read that will provide some guidance as to number of turns, cap value and expected frequency range?

12"
Antenna will be very narrowband you will have to tune it.

Check Q with L/C
Rx is OK,
Tx can create harmonics as ferrite is non-linear.
Bigger diameter only keeps ther ferrite out of saturation/non linear region.

Most of the remote control transmitters use a 1 transistor LC oscillator that is turned on and off by a digital pulse stream. The spiral on the circuit board does double duty as the frequency determining inductance for the oscillator, and acting as a small loop antenna.

>"dipole" 66' X inches per leg, center fed with 300 Ohm twinlead

Hi Gary, A classical Zepp or Zepplin antenna is not center fed. I thought they were end fed and hanging down from the airships of WW2.
If you have the room for a full sized 80m dipole, use 300 ohm or 450 ohm ladder line with a choke balun (1:1 W2DU) and an antenna tuner. Will work great on all HF bands. Don't mess with a 4:1 balun. Doesn't provide enough benefit for this type of antenna.
The best "all band" antenna I have ever used was a 100' dipole, high as possible, fed with ladder line and a tuner. Don't know if the 1:1 balun I used did much.

Hi Roy,

Administrative offices are frequently the poorest source of legal
information - especially when worded as vaguely as above.

Instead, Court records show a vastly different interpretation:
"Even though infringement is found, one factor that may negate
willfulness is a bona fide attempt by the alleged infringer to
design around the patent. ... The Federal Circuit reversed,
stating:
This court has indicated that the incentive to "design around"
patents is a positive result of the patent system.... One of
the benefits of a patent system is its so called
"negative incentive" to "design around" a competitor's
products, even when they are patented, thus bringing a steady
flow of innovations to the marketplace. It should not be
discouraged by punitive damage awards except in cases where
conduct is so obnoxious as clearly to call for them."

The obnoxious conduct, in this case, was the licensing of a technology
to then develop patents that would then render the original useless as
a commodity (the only value of a patent). In other words "bad faith"
agreements.

The ruling is from one of many (883) articles on the web specifically
directed toward the State Indus., Inc. v. Mor-Flo Indus., Inc. case

More on willful infringement:

"Patent law encourages competitors to design or invent around
existing patents." See, WMS Gaming, Inc., 51 U.S.P.Q2d at 1396
(Fed. Cir. 1999). Thus, a good faith attempt to design around the
patent will generally negate a charge of willful infringement,
particularly if advice of counsel is sought during the design
process. See, Braun, Inc. v. Dynamics Corp. of Am., 975 F.2d 815,

823 (Fed. Cir. 1992); Read, 970 F.2d at 828 (Fed. Cir. 1992).
Indeed, even in the absence of advice of counsel, a sincere
attempt to design around the patent may negate willfulness. See,
Rolls-Royce Ltd. v. GTE Valeron Corp., 800 F.2d 1101, 1109-1110
(Fed. Cir. 1986).

By-and-large, it is overwhelmingly clear that all such cases brought
and LOST were against commercial interests and not lone individuals.

It seems to me that the raison d'ï¿½tre of this body of amateur radio
activity is to improve designs - at least Rhetorically.

I suppose suit for slander or defamation stands a better chance. ;-)

156. Wireless Innovation Contest - Get your innovation noticed!

Newsgroup: rec.radio.amateur.antenna
Date: 2005-01-05 02:26:39 UTC
From: Andrey <a8421@intergate.bc.ca>
Message-ID: <10tmk1sr8d53256@corp.supernews.com>
Source record: 84294

Get your innovation noticed! Submit it to Wireless Innovation Contest.

If you've created something that's really making a difference, then we want to hear about it. And, more importantly, we want to tell the World about it.

2005 Wireless Innovation Contest takes place in Vancouver, BC Canada. The 2005 Wireless Innovation Contest is out to prove how wireless is changing the world. It could be a successful product, an enterprise solution that saved your customer thousands of dollars, a government solution that helped save lives or enhanced education or an entertainment solution that has made the world a lot more fun.

Nokia, Telus Mobility and other Industry Partners throw Support Behind the Contest this year. A panel of industry leaders will judge each entry and decide on a winner and runner-ups. Winners of WIC 2005 are rewarded with targeted exposure in media and at trade shows, inclusion in a specialcase study publication and a one-hour mentor session with the panel of judges.

More information is available at www.winbc.org/contest

So by your interpretion of the law, it's ok for anyone to make a copy of a patented item for personal use (which was the original statment)? That's not obvious to me from the short quotes you gave, and I'm surprised in any case that you can draw such a sweeping conclusion from a couple of paragraphs. But then, I'm not a lawyer. Are you?

So Ken

A couple years ago I wanted to cut a recieving dipole for a specific SWL frequency (somewhere in the 15MHz band). I calculated the length carefully, and then stapled the wire antenna to my fence (to be stealthy). Fed it with RG-58, it should have worked pretty good, I thought. (even though it was only abt 5 ft up).

After using it for a bit, I disconnected the coax shield at my reciever, and the recieved signal jumped by a couple S-units. Surprise!

Here's what I decided: If I were to transmit to that dipole nailed to the fence, I would do a lot of heating of the wood, and much less heating of the ionosphere. Recieving would work the same.

Conclusion: A wire antenna located near a lossy medium like your deck won't work like you want it to.

Message-ID: <n0KCd.752277$mD.196592@attbi_s02>
Source record: 84297

Hi Gang.

Sometime in the distant past (in the 50's) my property was owned by a ham. He put in two poles, six inch pipes 50 feet high and 170 feet apart, to fly an antenna. They once had cables for hoisting the wire to the top, much like a flagpole, but they have weathered and fallen. There are pulleys at the top, and stanchions (where you tie the rope off) about midway down the pole.

I need to do two things:

Get the ropes back in place, and
Lower the stanchions to a more usable level.

And I have no idea how to do the former. How do I get ropes back on those pulleys? Are there flagpole-riggers who shimmy up the poles, or do I hire some brave local kid to risk his neck in the attempt? I really want to get a proper antenna up there, and don't mind paying someone who does this, I just don't know who to call.

If I were going to have some kid shinny up the pole I'd have some friends
at the base with some form of guys which you cold slide up the pipe as
he climbs for stability. You might want to set one set of guys about
half way up. Assuming the poles are steel, and in good condition, you can
remove the guys as he comes back down.

If the LCD that you remember was an old passive matrix type, you may be pleasantly surprised by a modern active matrix (TFT) display.

LCDs are still not as bright as a CRT, though, so I was more than half-serious in suggesting an awning for shade.

Whose making interpretations now? :-)
The findings already answered the matter with sufficient emphasis as
to intent. If you cannot distinguish intent, you should seek legal
counsel.

Your response reminds me of the satire in "Hitchhiker's Guide to the
Galaxy" where the planet Galafria suffered from serious continental
erosion from too many tourists. They were warned that visitors had to
weigh as much when they left as when they arrived, and were thus
warned under penalty of surgical balance to take care to obtain a
receipt each time they visited the 'loo.

165. A very Popular Misconception

Newsgroup: rec.radio.amateur.antenna
Date: 2005-01-05 09:24:55 UTC
From: Reg Edwards <g4fgq.regp@ZZZbtinternet.com>
Message-ID: <crgbp7$5db$1@titan.btinternet.com>
Source record: 84303

It is a very popular misconception that METAL in the vicinity of a ladder-line or open-wire line causes bad loss in the line.

It doesn't! Simply because metals have a very low resistance. Line conductors are made of it.

There IS an effect however, the magnitude of which depends on whether the foreign metal is in small pieces, as with staples or clamps, or continously distributed as when an insulated line is lying across a galvanised corrugated iron sheet, touching only at intervals.

Each of the two wires has a stray low-loss capacitance to the foreign metal. The pair of stray capacitances are in series which approximately halves the effect. The effect is a decrease in Zo.

Now line attenuation in dB per 100' is directly proportional to R / Zo where R is line conductor resistance. So the small extra capacitance does in fact result in a negligible increase in line loss. But even less loss is induced in the foreign metal especially if it is bulky or has a large surface area and is not resonant.

The small increase in capacitance is equivalent to an un-noticeable shift in tuner settings.

Where loss DOES occur is when the close-by foreign material is lossy such as the surface of damp garden soil. Loss falls off again when the material is an insulator such as dry sand although the increase in capacitance still occurs.

Maximum loss occurs when the foreign material has a resistivity which fortuitously "matches" into the line impedance.

But the existing rule still applies - avoid suspending twin-line nearer to ANY material less than 3 or 4 times conductor spacing over appreciable long distances. Even though copper sheet may be OK.

I also agree with cherry picker idea. If you are comfortable going up in them, you can even rent one of these and do the work yourself. Of course it is still always wise to have a safety man on the ground if you go up yourself. One of our local hams rents one whenever he needs antenna work done and gets one of the club members to go up in it as he is way to hefty to do this work.

<g4fgq.regp@ZZZbtinternet.com> wrote:

Just to add to the fray, here is my recent experience. My antenna is
a 200 foot dipole (flatop) at 45 feet center fed with about 50 feet of
450 ohm ladder line down to a balun then 20 feet of 72 ohm coax into a
homebrew L match tuner. It tunes 160 thru 10 meters and works very
well on all bands. I tried different balun configurations with varied
results. Settled on a 4:1 powdered iron (red) core 2 inch toroid of 8
bifilar turns number 12 wire, the center tap connected to the coax
shield and also to a separate ground rod 2 inches below the balun.
Good results on the air and no RFI in the shack. A 1:1 balun on the
same core tuned up OK, worked on the air OK but produced RFI. A
coiled up coax choke balun gave bad RFI into phone, sterio and TV.
Tried 6 mix43 ferrite sleves on the coax up near the ladder line with
no balun, this was worst of all grounded or ungrounded, producing
severe RFI, in fact the 600 watt linear was unusable on 80 meters due
to RF into the rig. So they all worked, but the 4:1 grounded balun is
best by far in my situation. Now if I was to put a half twist in the
ladder line and take up religion, that could all change.

This ain't a federal job.

<rant>
If it were, you'd have to file an Enviromental Imapct Statement before
ever modifying the existing 'structures, you'd have to file a Non-
Discrimination Certificate, you'd need to hire a Saftey Compliance
Office, you'd need to do Wetlands Mitigation, you'd need a review
by The Army Corps of Engineers, you'd be required to do a floodplain
study, you'd have to file I-9 forms for each member of the 3-man crew,
and for some vacuous reasoning du jour, you'd need to be strip-searched
by The Department of Homeland Hysteria, etc., u.s.w.

Thank gawd it ain't a federal job.
</rant>

Yes, of course, be safe! Think safety.

Gary, I have a kit #835 from the Wireman that is a 4-1 balun -- it
uses two pieces of paralleled coax with ferrite beads. That is the
closest I've heard to the twin coax deal you describe above. Don't
know that you really need such a balun -- a standard single coil of
coax, or a W2DU type with ferrite beads on a short length of coax, or
the 4-1 balun that comes with your tuner -- any of these should work
with your center-fed dipole. Right now, my 130 foot dipole with
ladderline works best with my tuner's built-in 4-1 balun.

I'd just put the antenna up, and then experiment with different ways
of feeding it to your tuner -- I imagine every installation will work
a little differently depending on how high your antenna is and how
long your ladderline is.

Richard,

You have significantly misinterpreted the concept incorporated in "State Indus., Inc. v. Mor-Flo Indus., Inc".

The issue in this case, and the others that reference it, is the question of "willful" infringement. The infringement by itself is not the issue.

Willful infringement allows for punitive damages and other monetary claims. Non-willful infringement would generally carry only "cease and desist" type of remedies.

"Willful" means that one knows about the existing patent, or should have known about it.

The whole issue of "design-around" relates to the case where the infringer knew about the patent, attempted to design around it, and failed to sufficiently differentiate the new item, thereby infringing on the patent. The infringement stands, but since an effort was made to design around the original patent the infringement is deemed to be not "willful". The second party is not granted permission by the courts to continue to infringe on a valid patent.

I believe Roy is completely correct in his statement of the wording of the patent law, and court interpretations to do not appear to change the basic concept.

In a practical sense it is unlikely that anyone would want to sue an individual one-time infringer making an item for his own use. It is still a violation of the patent law to infringe, however.

Hi Bruce

Are you familiar with the way Pony Clamps work?

It would save a lot of time in telling you how to make a pair of metal pole climbing dogs.

Mine are just twin steel plates with an angle iron welded under them for added support. 1/2 way open they form what looks like a heart, closed they form a hole shaped like an elipse.
You open them and slip them around the pole and close them, one on each side. There is a small iron strap the toe of your shoe slips under. As you lift your foot, you lift the dog, keeping it level. Before you put your weight on it, it tilts downward slightly, locking it to the pole. Once it's seated firmly you lift the other foot, sliding that dog upward keeping it horizontal until it touches the first then let it tilt downward slightly, locking it to the pole. Keep repeating this process until you get to the height you want. Coming down works the same way, lift your foot to unlock it, hold it horizontal and move it back down the pole, locking it each step of the way. It locks automatically and easily to the pole.

There is only one axle bolt in each unit that passes through the angle iron. This allows the top sheet of steel to swing open and shut for installing it on the pole. Being I'm the nervous type, I drilled two holes on the outbound side and use a short bungee cord to make sure it stays shut. But, once around the pole, the heart shape keeps it shut. Mine is sized for 3-1/2 inch OD down to 2-1/2 inch OD poles.
They CANNOT be used on push-poles or thinwalled pipe needless to say.

Hi Reg

Thanks for the post!

I just wanted to add something that has never made sense to me.

I had a section of ladder line that I affixed to the roof joists under the eaves using thumb tacks. Three of these thumb tacks kept coming out on me, the rest held just fine. It was always the same three.
The last time I used three push-pins with plastic heads and found the heads missing from the push-pins shortly thereafter.
It wasn't until I discovered the puddles of plastic on the ground that I realized that they had melted. Yet the ladder line itself seemed unharmed.
So I picked up a small box of nylon screws at the hobby shop and replaced all of the thumb tack and the three push-pins with these nylon screws.
After doing same, I had to make adjustments to my tuner on a few bands.

After that I never had a problem again!

I never noticed a change in transmission or reception before or after. But feel the RF is what caused these thumbtacks to keep coming out, probably burning the hole in the rafter larger and larger each time and that could be what melted the heads of the push-pins off.

The three thumbtacks that kept coming out were equal distance from each other, about 64 inches apart. There was a thumbtack every 16 inches along the part of the ladder line that ran under the eaves.

Hi Gene,

As I pointed out that very term, and it is included in every quote, it
hardly constitutes my having missed the issue. I even commented on
the distinction as it applies to the pursuit of Amateur Radio, in that
our service is in improving design. These Cassandra appeals to the
contrary rather misses the mandate of our privilege.

Hello OM,

There are many omnidirectional designs. There are many multi band
designs. There are very few that accomplish both successfully for a
wide variety of signals over a wide variety of frequencies.

Wide band antennas like a Discone are really only useful over roughly
2 or 3 octaves (doublings of the base frequency). They are often
specified by impedance match; and as correct as this specification is,
it is not complete. You also need to consider the angles that it is
most sensitive to. For the first 2 or 3 octaves, this would be toward
the horizon. For the 4th and higher octaves, the most sensitive
regions for listening begin to climb higher into the sky. Who do you
want to listen to? Where are they? This is the meaningful relation
you should seek to optimize.

==========

Hi Gary,

Very peculiar. But what it wasn't due to was I-squared R losses in tiny metal objects such as thumb tacks. You were not working in the GHz range.

Always the same set of tacks could have had something to do with voltage standing waves on your most-used favourite band.

The structural material was timber which has a highish dielectric constant and a poor power factor.

A thin insulating material on the metal pins would not make much difference.

Tacks and pins are very small and pointed. The voltage stress would be very high in a very small volume of timber. Arcing could possibly, but need not occur. But only a small amount of energy is needed to take the tacks and timber up to a high enough temperature to dry out the timber, contract the timber, and allow the tacks to fall out under weight of the line and gravity.

And as mentioned in my first message, the poor power factor or resistivity of the timber at HF could have resulted in an impedance match between the timber and line Zo.

You didn't burn the house down because of your gravity-operated safety precaution. ;o)

I would guess you were using more than 100 watts.

Reg, G4FGQ

As I read the findings, they seem to state that one cannot be held culpable of "willful infringement" of a patent if one builds a version of the patented invention *and* makes a good-faith effort to modify it so that it does not actually infringe on the patent claims. If the changes aren't actually sufficient to avoid infringement, the fact that you *tried* to avoid this is enough to keep your infringment from being "willful".

I didn't see anything in the findings which absolves anyone from infringement (willful or otherwise) if one reproduces a patented invention for personal use and does *not* make a good-faith effort to change it to avoid patent infringement.

Ah... you're thinking... FM broadcast range is 88-108MHz... with a 10.7MHz
IF... a high side LO is at ~98-118MHz, easily landing within the aircraft
band (which is... 108-??? MHz, right?).

Nah, we're all just becoming specialists. Colleges today have their various 'electrical engineering tracks' where you choose between, e.g., power, communications, digital logic, etc. -- I think that change come about some 20? years ago now.

> We can do our bit in the world of Ham Radio by encouraging

Unfortuately it can be difficult to motivate people to study the innards of radio when you have to explain to them that a modern cell phone has perhaps some 100 man years of engineering work in it -- and that any attempt to apply some of this same technology to amateur radio is going to be met by protest as well!

That's because they're so expensive to build. You'd probably never finish designing something like a modern RF IC if all you could do was design it on paper, build it, probe around a little to figure out what it 'really' does, and repeat.

Likewise, few companies can afford to design the autopilot for a jet without a great deal of simulation first. :-)

Dave,

With reference to your last sentence:

Did you see anything in the findings which absolves anyone from
infringement (willful or otherwise) if one reproduces a patented
invention for personal use and *does* make a good-faith effort to
change it to avoid patent infringement?

I found nothing that says infringement itself is somehow canceled. Only "willful" infringement is negated. Otherwise virtually all patents would be useless. One could always claim some good-faith attempt to change the patented item.

Again, in practical terms for an individual radio amateur it is unlikely that there will be any *legal* consequence from making a single copy of a patented item for personal use. However, it is still an infringement. The morality is up to the individual.

185. Source tracking with dish antennas

Newsgroup: rec.radio.amateur.antenna
Date: 2005-01-05 20:15:33 UTC
From: Joel Kolstad <JKolstad71HatesSpam@Yahoo.Com>
Message-ID: <cdydnYfnJJZ-10HcRVn-vg@comcast.com>
Source record: 84224

Hi guys,

I saw the Australian movie, "The Dish" over the holidays. It's about the Parkes Observatory and the large dish antenna used to relay video, audio, and telemetry feeds from Apollo 11 in 1969 back to NASA.

At one point in the movie, they lose track of where Apollo 11 is and have to scramble to manually point the dish to get a signal again. However, once they DO manage to get a signal, they flip a switch and the dish continues to automatically track Apollo 11.

I'm curious... how is this down? 3 or 4 slightly offset (from the dish's central feedpoint) receivers, the outputs of which are compared to determine which way the transmitting source is 'drifting' (then feed back to the motion control system to move the dish that way)? Or is there a simpler means?

Thanks,
---Joel Kolstad

By counting on the gulibility and limited education of movie audiences. :-)

The way a Hughes Radar system I once worked on did it was to spin the
horn in the dish focal point. The horn was E V E R S O S L I G H T L Y
off center in its axial alignment. The receive signal strength was
constantly compared against a servo feedback from the horn assy. to
determine which way (what angle) the signal source was drifting.

In a system that was polarization sensitive, I guess one could "joggle"
the position of the horn assy. and achieve much the same results.

193. HF antenna and Power line ?

Newsgroup: rec.radio.amateur.antenna
Date: 2005-01-05 21:14:45 UTC
From: Thierry <"See LUXORION website">
Message-ID: <41dc58c6@news.vo.lu>
Source record: 84232

Hi,

With a friend we have to install a beam near a HV Power line (we ignore its power) located 300 m from the QTH.

Has someone among you a chart or table listing the EM field and Electric field of various HV power lines ?
I know that a HV power line (I don't know its power) displays e.g. an EF of 10 kV/m and an EM flux density of 10 microT.
and that the field decreases like 1/r^2 and that there is a epidemiological risk from 2 miligauss.
I also know that the administation denies any construction in the 50m around such HV line due to the risk for the health
But these are all data I have. Not enough to appreciate to risk of this specific installation.

My questions are :
- Is there a risk that this HV power line disturbs DX QSOs in HF bands (and QSO in VHF, but here I doubt much)
- What is the risk for the health at such a distance according to the voltage ?

Thanks in advance

Hi Gene,

"Patent law encourages competitors to design or invent around
existing patents." See, WMS Gaming, Inc., 51 U.S.P.Q2d at 1396
(Fed. Cir. 1999). Thus, a good faith attempt to design around the
patent will generally negate a charge of willful infringement,
particularly if advice of counsel is sought during the design
process. See, Braun, Inc. v. Dynamics Corp. of Am., 975 F.2d 815,
823 (Fed. Cir. 1992); Read, 970 F.2d at 828 (Fed. Cir. 1992).
Indeed, even in the absence of advice of counsel, a sincere
attempt to design around the patent may negate willfulness. See,
Rolls-Royce Ltd. v. GTE Valeron Corp., 800 F.2d 1101, 1109-1110
(Fed. Cir. 1986).

>I found nothing that says infringement itself is somehow canceled. Only
>"willful" infringement is negated.

Common infringement cases, as they occur, are ruled upon their merits.

>Otherwise virtually all patents would
>be useless. One could always claim some good-faith attempt to change the
>patented item.

This marks the issue of protection offered, but NOT GUARANTEED. And
again, if it goes to court, it will invariably be between
manufacturers (or the patent holder and a manufacturer). The courts
are quite competent to smoke out the rats.

There is a special case whereby a manufacturer (or anyone for that
matter) CAN build and SELL a patented item irrespective of the patent
holder's wish IFF such a product was available before the issuance of
the patent, and the manufacturer does not diverge from that prior
issue design. This, in itself, proves the poor quality of
bureaucratic interpretations of the law that tar the subject with a
large brush.

> (Fed. Cir. 1986).

As I understand the situation from my reading (and I am by no means a lawyer, hence my understanding bears no legal weight at all), there are two issues involved:

[1] Does it infringe? Are you, in fact, actually reproducing an invention which is patented?

If you are, then you can be subject to penalties (e.g. the original manufacturer's loss of profits due to the infringement), and/or become the subject of a court judgement which forbids you to continue manufacturing the infringed invention.

[2] Was the infringement "willful"? Was it a knowing and deliberate infringment?

If so, the court can increase the amount of damages awarded to the inventor(s), up to the point of treble damages.

As I read the rulings cited above, they have to do with the issue of whether an infringement is willful (and thus subject to increased damage awards) if the infringer had made a good-faith effort to "design around" the patent. The rulings above, as summarized, don't seem to deal with whether *infringement* itself occurred... only whether the infringement was *willful*.

So - if you start out in an attempt to "design around" someone else's patent (creating a similar invention which does not actually

infringe), and you use good faith in this attempt (which would
probably mean a competent engineering approach, plus advice from
competent counsel), and you think you've modified the invention
enough to avoid infringing, and a court rules otherwise, then:

- You'd still be infringing, and
- The court would probably rule that your infringement was not willful,
and would decline to levy any increased penalties.

http://www.mmmlaw.com/articles/article_234.pdf describes one such
case... Polaroid vs. Kodak.

>>Otherwise virtually all patents would
>>be useless. One could always claim some good-faith attempt to change the
>>patented item.

>This marks the issue of protection offered, but NOT GUARANTEED. And
>again, if it goes to court, it will invariably be between
>manufacturers (or the patent holder and a manufacturer). The courts
>are quite competent to smoke out the rats.

Very probably.

Oh... back on the original question of "building for personal use."
It appears that this question depends on where you are. The U.S.
doesn't have a "for personal use" exemption, but it seems that most
E.U. countries do, and that in these countries a patent infringement
doesn't exist unless the infringing products are actually being
offered for sale. Quite a sensible approach, I think.

Hi Charlie,
Great set up on the 5-BTV, I have the same antenna, but roof mounted. How does it do on DX, have you had a chance to work with it much? I've had fair success but am not completely satisfied. I think I need more radials (20 right now). I have a fan dipole set up for 20, 17, 15 and 10 meters and switch back and forth between them. Sometimes they seem about the same and other times one will be much better than the other. I've got a lot to learn about antennas. Congratulations on upgrading to Extra, I'm AD5SM just 21 letters ahead of you. I upgraded in October, so you must have upgraded very recently. Hope to work you on the air someday.
Rob

Roger,

Since you selected the Hustler 75 meter Super Resonator to make your Hustler 4-BTV into a 5-BTV model, I would add guys (as recommended in the Hustler installation manual) due to the weight at top and overall length of antenna. 3 or 4 guy wires should work well.

My primary HF antenna is a trap 80/160 meter dipole.
It works good for those bands with no need for a tuner.

I'm shopping for a new HF rig, a TS-850SAT and I was
wondering how good the built in tuner would work with
the 80/160 antenna on higher bands, mainly 40/30/20m.

Anyone know?

Ken KG0WX

Hi Rob,
As far as DX goes I keep my DX Logbook online at www.ad5th.com/logbook.html
I have been having a ball working DX on 75M at night. No..I did not
recently upgrade to Extra. I got my No-Code Tech in May 1995 and upgraded to
Extra in November 1995 so I have been an Extra over 9 years. I did recently
move to 5 land and so when I updated FCC I asked for a 5 land call.

Thanks for your remarks and I hope to catch you on the bands

Hi Guys,

Back when I designed the UFDR for the 757/767, they were the first
airplanes designed entirely in software (conventional drafting went
the way of the Dodo). Today's 7E7 was entirely modeled in software if
I'm not mistaken.

The Zepp is an end-fed 1/2WL antenna. The Double Zepp is a center-fed
one wavelength antenna. An Extended Zepp is a 5/8WL end fed antenna. An
Extended Double Zepp is a 10/8WL center-fed antenna.

At my QTH, the power lines render a vertical virtually useless. I
suspect it is the vertical ground wire on a pole-mounted capacitor that
is the culprit as it is close to 1/4WL on 40m.

Joel:

Go look up a tutorial on monopulse radar. It should include the methodology for deriving tracking information from the
signal phase and amplitude at the horn(s) or other antenna at the focus. I would try to explain it, but every time I do
I get something wrong.

Hi gang
I've been trading insults with many of you for more than a few years and I value you all, even Cecil.
Us Teasips need Aggies, and they need us, they just won't admit it.

Last week I dug the hole for the tower I promised myself 42 years ago.

Monday the backhoe truck broke down.

Tuesday another backhoe showed up but the operator didn't have the key.

Wednesday the hole got dug. It turned out a bit big, but you can't have too much concrete.
-It's a 48' Trylon self-supporting tower.

Thursday I waited all day.

Friday afternoon, after waiting all day Thursday, the rebar and tower base were installed and welded together.
-The tower base was plumbed with a laser transit.

Monday, 7AM, poured the concrete, done by noon.

After the two week cure, the crane comes.

More then.

I would suspect that once the signal is found, good old well defined
celestial/orbital mechanics takes over. Even good quality optical
telescopes have a drive that keeps the instrument pointed in the right
direction.

Of course the moon travels on its own orbit buts its path would also be
well known.

Some, not all.
Electrically desirable, but the main concern was making the base stable
during the pour.

Now I'm sinking an array of ground rods.

These guys build power lines, for God's sake, they're moonlighting.

Ever see how many frickin' towers power line engineers build?

Get a life.

This is a child's fantasy that's come to fruition after 42 years.

And if I save one sailor's life on the Maritime Net it's worth it all.

Can't say which is better.... but I've always been happy with the Diamond D130J discone antenna. It might be your best choice if you really want to put your scanner frequency range to full use.

sample info can be found at: http://www.grove-ent.com/ANT9.html

This is a case in point of specs-manship:
>Designed for use with wide-frequency coverage VHF/UHF scanners
>and receivers, the Diamond D130J Discone consists of 16 rugged,
>stainless steel elements and is capable of transmitting up to 200
>watts in the amateur 50, 144, 220, 432, 900, and 1200 MHz bands.
>
>As a receiving antenna, the D130J is omni-directional for continuous
> 25-1000 MHz (and above) coverage. A base-loaded, vertical top
>element is used as a low band (30-50 MHz) frequency extender.

In the 1200 MHz band (to which it will faithfully match), this antenna
is going on 4 or 5 wavelengths tall. This gives it strong gain -
STRAIGHT UP. If you want to work satellites overhead, great; if you
want to work a signal across town, deaf.

Hi Roy

Yep that was probably it. It is some way north out of Parkes near a
place called Alectown.

If you go to http://topoweb.lpi.nsw.gov.au/run.htm and zoom up on about
148.2639E 32.9975S, thats where the dish is. Its about 300km WNW of
Sydney so it isnt exactly in line with a trip to Charleville.

There is a smaller comms dish in a place called Moree. About 400km NNW
of Sydney. Nowhere near as big as Parkes tho. I think the only other big
dishes are south of Canberra. There is however one or two Mills Cross
arrays out there but they of course arent disk shaped!

Amd there is another dish array (6 of 22m dia) at a place called Narrabri.

http://www.parkes.atnf.csiro.au/ is the dishes actual website c/w
pictures to check out.

Cheers Bob

Thanks Cecil and to all who responded, I think I'll just put up a
center fed dipole and feed it with twinlead or ladder line and then
use the 4:1 balun in my antenna tuner.

Hah! I remember Moree. One of the folks in the helicopter (Aerospatiale Ecureuil -- very nice machine) had a friend who lived there, and we stopped there to refuel. After we took off, the fellow with the friend gave the pilot regular car-driving-type directions ("go down three blocks and turn left. . .") as we followed the road at a low altitude. When we got to the friend's farmhouse, we circled to make sure there were no hazards, and landed in the farmer's front yard. You should have seen the look on his kids' faces! We went in for coffee, came back out in a few minutes, and continued our trip. As a funny-talking Yank, I was the novelty of the group.

Anyway, the dish I saw wasn't directly on our path, but off to one side a bit. I'll have to dig out my notes and see if it might have been the one at Moree. I might be able to estimate the diameter if I can find the picture. Small world!

A couple of anecdotal experiences.

Back about 15 years ago, I was doing some high-power RF exposure testing on a cruise missile. I had a 300 watt TWT amplifier feeding an X-band pyramidal horn antenna through waveguide. I went into the chamber to rotate the antenna polarization, and put my left hand across the antenna aperture. I immediately thought it was strange, as warm air was blowing out of the horn. But that was impossible, since the horn had a mica window across the throat! Duh, I had left the amplifier turned on! So I can report that tissue heating is an almost pleasant experience (very short term!), quite akin to the warm-air hand dryers found in some washrooms.

I also recall reading a letter to an RF trade journal, where an experimenter was relating his experience on a WWII research project. His team of four was working on waveguide hardware design, observing high-altitude, high-power

breakdown problems. He related that the team had set up a horn antenna within a large glass bell-jar (so that they could pump it down to altitude). The horn faced horizontally out of the jar, and the team set up a small telescope just outside the jar so that they could look down into the horn throat and feed to observe arcing. He said that they would change observers when their face got too hot!

There's nothing wrong with doing a lot of modeling. OTOH, Boeing didn't go from the computer model directly to production. Computer models don't do very well in predicting the unexpected; things like digital designers discovering the concept of parasitics ("There's nothing in my design that generates 832 MHz!") or mechanical designers exploring the wonders of RF stray coupling paths ("The RF gets from this compartment to that compartment through a BOLT?!"

My initial point was that wondrous and amazing things can be proven through software being pushed to the outer edges of its parameters. Before you invest in several years of modeling, someone needs to take a whack at a brassboard model to calibrate the sanity of the software.

A few years back I opened the highish-level kitchen microwave oven door and felt what seemed to be a warm breeze of air on my face and especially round my eyes.

I immediately recognised the sensation felt when standing in the beam from the non-rotating dish of a 3 GHz, 50 Kwatt radar equipment during WW2, some 50 years before.

I very fast switched all power OFF. The safely mechanism must have been defective. It may have been a good thing my XYL had not opened it.

There were no after-effects except on my bank balance for a new oven of different make.

That is a very popular configuration and works for a lot of hams. You may need to change the length of the feedline for optimum operation. Some ideas and information are available on my web page at http://www.qsl.net/w5dxp/notuner.htm

One case where a 4:1 balun doesn't function well is on dipoles that are less than 1/2WL long. For instance, the impedance looking into the feedline for a 102 ft. dipole used on 80m may range down to 10 ohms. A 4:1 balun tries to take that 10 ohms down to 2.5 ohms. Antenna tuners are inefficient when trying to match such low impedance values.

You will find that your scanning needs are probably quite narrower than the capabilities of either receiver or antenna. The stolen trademark "Scantenna" which is widely produced (although no longer by Radio Shack, who was forced to discontinue marketing this design) has been highly favored by scanner enthusiasts for it's confirmed superior performance over Diamond or any other standard discone antenna. It is not better than a standard discone in a few narrow bands, but in bands most popular for scanner receivers (118 Mhz - 860 Mhz) it is vastly superior. Other limitations of the Scantenna design are it's lack of transmit capability, and weak open-rolled aluminum tubing design, which fold over in winds >50kts. At least one hobbyist I know personally claims it is slightly directional, and he has it mounted on a channel-master rotator for this reason. I have owned several and confirm the significant extended reception in most vhf and uhf bands over various standard discone antennas.

It would probably tune, but it's not really meant to feed "all band"
antennas.
I wouldn't plan on that myself...Those tuners cost too much to abuse in
that
manner...They are really meant to be used as line flatteners. IE: give
you a
wider usable bandwidth with the solid state finals. Your load should be
in
the ballpark to begin with...IE under maybe 5:1 or so??? MK

After reading numerous posts, I built an EDZ for 20 using the '450 ohm' ladder line and coax balun approach. Maybe I got lucky, I don't know but when I hooked up the antenna analyzer I was surprised to see an SWR of 1.3:1 at 14.030 and the impedance was around 51 ohms. So far it does outperform my old G5RV by a fair amount to it's favored direction (SW or NE). The antenna is at 35 feet (wish my trees were higher, but they aren't). The only downside I can see is this antenna has a very narrow beamwidth and the nulls are quite pronounced, but that's what the G5RV is now for.

I use the design found at : http://www.hamuniverse.com/jpole.html
Standard 1/2" copper pipe with acid-free solder, no balun, no choke, and approximately 70' of Belden 9913 feedline. Grounded roof top mast uses #4 bare copper lightning down conductors in two directions, coax is shield grounded at ground level, then to an I.C.E lightning surge arrestor, then to a 25w marine vhf transceiver. The J-Pole is bench centered on 156.800 Mhz and allows 18-23w output (at the transceiver) across the vhf-marine band. Very experienced antenna builders on this group have explained that my results without a balun/choke at the feedpoint is a combination of luck concerning feedline length and operating bandwidth. Accordingly, your results would most likely vary, but the design is a confirmed performer.

This is an excellent antenna that will serve you well over all HF bands, including 6 meters. I use this antenna with good 300 ohm line purchased from Davis RF, and a Radio Works Remote Current Balun. From there I use about 4 feet or so of LMR400UF low loss coax to the rig. The autotuner in my FT-920 will tune this antenna flat on most bands. I do need to use an external tuner on 30 and 10 meters, but this is easily acomplished by a 2 position coax switch. This system has produced the best results of any setup I have had in 40+ years as a Ham.
Unless you are real certain about the behavior of that coax balun, I would invest in either a Radio Works, or DX Engineering balun of known repute. Then get on the air and be amazed.

How do you "adjust" this antenna for optimum swr? Would it change the
results using "qwick connect" fittings instead of welding/soldering?

Are the end caps that are soldered on included in calculating the
length?

I've tried many rigs and the tuner of TS-850SAT is one of the best internal
tuner I've ever seen, but you can not be sure that it will tune the high SWR
of your antenna+cable until you will try it...

Odds are that your feedline is a multiple of half-wavelengths
plus 0.2 wavelength. If you know the VF and length, it would
be interesting to calculate how close you came to N.2 wavelengths.

>Please forgive me if these are elementary questions.

Hi OM,

We can forgive the questions, but they are far from elementary. In fact, there are so many variables to consider, that it often makes such questions hard to answer without going into a considerable length of constraints.

One simple response, however, is that for VHF/UHF, stainless steel is hardly the most complex issue - this has already been noted here in discussion. The remaining characteristics of length, size, and distribution of elements has as many answers as answerersï¿½.

To put it bluntly, you should put some effort into coming to terms with modeling software to appreciate the variety of answers and their ramifications. Getting this same education through single one-off questions could take many, many years.

Another way is to simply pick a design, and build it. When you discover what's good or bad about it, THEN discussion could more easily respond to what you have and what you need to do. Experience is the great leveler against "what-if." One notable aspect of this past time is you are NOT going to do this once! So you may as well do something and expect you will do some more (and more...).

Just wondered why you needed the coax switch. If you put the external tuner between the FT920 and the antenna couldn't you just bypass the FT920 tuner and switch in the external tuner for 30 and 10 and visa versa for the other bands?

I do this with 2 external tuners. I have an antenna with a similar situation to yours. My TS870 will autotune ok on 40 thru 10 but not on 80 or 160. I just daisy chained two external tuners (one pretuned to 160 and the other to 80) between the TS870 and the balun feeding the open wire feedline. I simply switch in the needed tuner and bypass the other two. Why *2* external tuners? It makes for quick band hopping. You switch bands, hear em, push a few switches, and work em... ;)

wrote:
>What other reason could there be?

Hi Bill,

The usual reasons: Brighter; Lower Power; Longer Life; Lower Loss - as long as the added complexity is offset by the economic gain. If they were dual diodes connected parallel and reverse polarity driven by AC, then the advantage would be reduced cathodic reduction of contacts exposed to water (for years I noted how the poorly built US cars went through tail lights that burnt out due to corrosion). AC systems also extend lifetime to conventional filament lights.

Now, by Brighter, this is not due to higher peak currents. LEDs don't really peak as well as other devices. Their overdrive capacity is somewhat limited. Rather, the Brighter is a physiological response. It is actually the same brightness, except we perceive it as brighter (although, if the period exceeds the Stroud Moment this may no longer hold). Light can be frustrating to compare to measurements, because impartial measurements will reveal little difference to what we perceive to be dramatic change. One of those tricks of the brain.

Yes the caps are part of the electrical length. Tuning is accomplished by adjusting the tuning bar (dimension "C" up or down between the two vertical elements. Very little adjustment is required from the design dimensions for "bench" swr. Of course that would need to be tested as installed is you want to know the actual output in watts at the antenna. Mine required no field adjustment.

Jack Painter wrote:
"An awful lot of engineers have accepted the findings already, and
specify blunt-tipped rods on new construction.:

They should specify what works.

Suppose a charged cloud arrives overhead and no lightning immediately flashes. If the charge is positive, it attracts electrons in the earth ond other conductors nearby. These electrons strain to reach the cloud, runnibg through conducting bodies to get closer to the positive charges overhead. The blanket of air insulates between the charges of opposite polarity. The field grows faster than these charges are neutralized. Sooner or later, the air at a high point starts to ionize (form a conductive plazma). Then, current flow starts with a flash and a bang. Thunder rolls as air rushes in to fill the void left by burnt atmosphere.

Suppose that a lightning rod is at a high point beneath the positively charged cloud as it arrives. Electrons are pulled up to its sharp point (electrons repel each other, ao they tend to concentrate on the outside of the rod and find the least outside opposing forces at the tip of the rod.

To avoid corona formation, some transmitting antennas are fitted with "corona balls" on their tips. This reduces the strain from a pointed tip.

On a lucky day, the cloud is discharged without lightning. On an ublucky day, your lightning rod may get pitted.

Best regards, Richard Harrison, KB5WZI

Thanks Reg

Never saw any damage to the ladder line, but figured it must be the
points along the line these particular thumbtacks were placed.

No power other than what the TS-830Sugar puts out.
But I was using a Tuner if that made any difference on the line.

Hi Richard,

So much of this breathless science of rounded tips alludes to the legitimacy of rare publications equal in scope and stature to those that announced the proofs of cold fusion.

Did Pons and Fleishman turn their hands to designing Lightning protection systems to redeem their credentials?

http://www.qsl.net/ares_d24/jpole450.jpg has plans for a 450-ohm ladderline j-pole which is designed for 2 meters, but also works on 440 mhz with low swr, probably at reduced efficiency, but mine still works there, okay. (I don't use a balun.)

Do a Google search -- there's no shortage of plans for j-poles.

You can ground the "crook" of the j-pole if you wish, or not; works either way.

You might also go to the web site for Arrow Antennas, and look at their dual bander j-pole diagram, if you're handy with metal...

I know that. The question was and is: WHEN DID THEY START
TIME MULTIPLEXING AUTOMOBILE TAILLIGHTS? I am asking for
information and it's perfectly OK if you don't know.

Constant current LEDs have been in use for years. But it's
just over the last couple of months that I have noticed
the pulse-width modulation on some automobile taillights.
I suspect it's only one or two manufacturers so far.

A 2m J-Pole used on 70 cm has a takeoff angle of about 47 degrees.
The gain at 15 degrees is more than 3 dB down. It works, but a lot
of the RF is lost at the higher radiation angles.

269. The planning permission

Newsgroup: rec.radio.amateur.antenna
Date: 2005-01-06 19:48:39 UTC
From: Simon Smith <s.Smith@btinternet.com>
Message-ID: <crk4mm$n48$1@titan.btinternet.com>
Source record: 84208

Well, I today decided to make a start in trying to obtain planning permission for my new Antenna - even though the "Permitted Development Rights" have been removed from our small Village in the middle of nowhere on Bodmin Moor in Cornwall -
First step was to fill in all four sets of application forms - the truth - the whole truth and nothing but the truth !! Then out in the wind and rain with a tape measure and try to measure up the length of the garden - distance from the house to the proposed site of the Antenna - Height of the house in relation to the height of the Antenna - and then go back indoors and start to draw it all up into a meaning full set of drawing. Four copies were needed. Next step. Try to find the digital Camera and wait for the rain to stop before taking a photo of the intended site. Lunch. Proceed to print photos - run out of ink. Install new print cartridge - and finally manage to get the whole lot ready for the "Council"
Proceed to Bodmin Council offices - where a nice young girl offered to view my drawings before accepting them for consideration. The first mistake I made was in using feet and inches. "Sorry - we only take metric" So I now have to re-do them all again. Next mistake "We Don't take them on graph paper" Third mistake was
"We need a picture of the "Ariel" Forth mistake was: "We need the drawings to be to scale"
Did Marconi have all this trouble with the "Council" ?
Here I am - now trying to re-do everything - to some sort of Scale. Wife moaning - Kids Moaning - cat climbing over all the drawings - Dog waiting to be walked..... TV blaring out .... Ohhh happy days .... I think I am going Crazy..... Beam me up Scottie.....
To be Continued.....

That might be it. It would be a convenient and efficient way of adjusting brightness. They also might be compensating for voltage and temperature by changing the pulse width.

I looked into the hazards of microwave energy quite a while back (mid-60s), when I was a radar technician. Some of the old-timers in Alaska had routinely warmed their hands by putting them in front of the feedhorn, but enlightenment had taken place by the time I was involved, and systems were interlocked to prevent accidental exposure. (I worked on heavy ground radar, with peak output power of about 5 MW, and average power of several kW.)

As far as I could determine, plain heating was the only bad effect that had been found. The main potential for damage was the eyes, where there are apparently not enough blood vessels to carry away the heat very fast. Internal organs were vulnerable to very high rate doses, because of the relative lack of nerves to communicate the problem before it got serious. They hadn't found any cases of permanent sterility, in spite of the pervasive fear. Heat can kill any sperm present at the time of the exposure, leading to temporary sterility, which is likely the source of the belief. Otherwise, all it was found to do is warm you up. As long as the heat doesn't build up too much, there was no lasting harm.

I'm sure there's been a great deal of research since then -- both microwave ovens and cell phones have become ubiquitous in the intervening years. I believe some research has shown potential harm in long-term cell phone use with the antenna very close to the head, but don't know if anyone knows the mechanism -- or how good the research is.

So my view of microwave energy is that it's something to take care with, but not to irrationally fear.

Well, errr, Bub, you ain't "tuning" a J-Pole by "...moving the coax up or down".

You 'tune' a J-Pole by whacking off, or whacking on 'calculated' lengths
of the 2 parallel pieces.

There be a difference between "tuning" and "Matching".

Hi Jonesy,

Like I figured, another sucker posting. Cadillac was doing this for
its 2000 model:

" The 2000 Cadillac DeVille was the first vehicle to go into
production that utilizes HB LEDs for its rear combination lamps
(RCLs) as well as for its CHMSL. Many of the benefits here are
intangible-examples are the "jewel like" appearance of the RCL and
the ability to provide the tail light function with a particular
shape associated with the DeVille line. There are several tangible
benefits that can be measured, however, including reduced
electrical load, reduced mass, warranty savings, and mass
production quality improvements.

Although the Cadillac DeVille is the only production vehicle with
a complete LED rear combination lamp assembly, several other
recent car makes and models have incorporated LEDs into various
signal functions. These are primarily limited production luxury
cars, such as the Mercedes S-Class, BMW 5-Series, and Nissan
Gloria."

On the Lincoln Town Car:

"light-emitting diode array on the rear of this vehicle in a
research project at California Partners for Advanced Transit and
Highways takes data from the wheels and brakes and sends a signal
to following cars indicating the acceleration and velocity of the
vehicle."

which, of course, fulfills your anticipation of subliminal CW
messages. ;-)

As the old adage goes "if you have to ask, you can't afford it."
rec.philosophy.automotive may provide more details - this is clearly
beyond the pale of electromagnetic anything from anywhere.

The good news is, the clerk is actually being rather helpful.
A less useful situation occurs when the clerk accepts anything
you deliver and then the council rejects the proposal due to
improper formatting.

Hi Roy, You can do all the above with a regular light bulb. I think the reason they use multiple LED's is to reduce the mean time between failures. If a regular bulb fails, you are dark. If half of the LED's fail you still have light. They generally have 20 plus LED's. in the stuff I have seen. Also, LED's tend to last than bulbs (I think)

Uhhhhhh Richard, like I figured, you have no clue. The subject is NOT LEDs used in automobiles. The subject is ***TIME-MULTIPLEXING*** of LEDs used in automobiles and there is absolutely no mention of time-multiplexing of the LEDs in your above posting, i.e. it is irrelevant to my question.

> On the Lincoln Town Car:
>
> "light-emitting diode array on the rear of this vehicle in a
> research project at California Partners for Advanced Transit and

Again, absolutely no mention of any time-multiplexing of the LED currents so your posting is completely irrelevant to my original question which continues to be: WHEN DID AUTO MANUFACTURERS START MULTIPLEXING THEIR AUTOMOBILE TAILLIGHTS. I suspect it was on the 2005 models and certainly not five years ago as you mistakenly assert.

I first saw a time-multiplexed LED taillight on my 2004 Thanksgiving trip to Memphis. I simply do not believe your assertion that time-multiplexed taillights have been around for five years. The

onus of proof is upon you and your above posting is certainly NOT
proof of time-multiplexed LED taillights.

Why do hams persist on using "tuned" radials on the ground? They cut them to "resonance" which means nothing. A wire cut for resonance on 40 meters and buried under 2 inches of soil is no where near resonant 7mhz. It would be much more effective if they just made all the radials as long as possible and forget this resonance stuff but no one listens.

Which is the best amateur-band automatic antenna tuner made, for use with a 160-meter inverted V with open wire feeders, to cover 160 through 6 meters?

Also, is there much perceptible difference in performance, loss, signal strength, etc. between the best of the best and the ones that are only average in quality, assuming that both will properly tune the antenna?

Message-ID: <1105069566.617343.144480@z14g2000cwz.googlegroups.com>
Source record: 84127

I'm designing a thingie that requires 20 to 24 ga 300 ohm flat antenna wire. I find it's a real PITA to separate the ends of the wire, trim that 1/4" of insulation out from between them, and strip the ends. Is there a tool that simplifies this job? If so, what is it called and where might I find it?

Thanks!

By microT I assume you mean microTesla. One Tesla is 10,000 gauss. So 10 uT
is 100 milliGauss, 50 times more than your statement about epidemiological
risk.

But I can't answer your questions. Sorry.

John

Use 300 ohm ladder-line (window-line). Remove the inside dielectric
with an Exacto knife and treat the remaining wires normally.

Most ATU's could tune your rain gutter with about equally bad performance
that you would get on any single antenna that you asked to service that
entire bandwidth.

> Also, is there much perceptible difference in performance, loss,

I have never read reviews that compared them against each other.
http://www.eham.net/reviews/ will display the comments you're looking for.
After eight months of use, I am completely pleased with my MFJ-994 600w ATU.

Hi Richard,

Your example of lightning was the opposite, and very rare, from the normal occurrence of lightning which is not positive-charged. You can read about the discovery of this rare form of positive-charged lightning at: http://www.ee.nmt.edu/~thomas/nyt/nytimes_lightning.html

As a thunderstorm approaches, preceding its arrival there is a "wave" of positively charged ions that roll over the landscape like a wave. Buildups of these positive charged ions do gather on objects, and there is little

favoritism that describes their formation on pointy or rounded objects, they attach to everything. Upward-flowing streamers are emitted from these objects as a negatively charged cloud adds its powerful attraction to these ions. This occurs from human heads, shoulders, lightning rods (of any shape) and your so-called corona balls that offer no protection from positive-ion streamer emission whatsoever. I would suggest that in this area, your recollections of early lightning theory require major updating, since it seems based in part on radio theory that never applied to lightning in the first place, however well intentioned many engineers in that field may have thought it so. Corona balls are examples of the antenna being in the bathtub and not influencing lightning in the least bit. Some things persist because people want them too, whether scientific support for them remains or not. Now, once lightning has broken down and been divided, lessened, etc, then it begins to take on a shape that fits in the bathtub. Be corona-ball happy then if you like.

The junk-science of early-streamer-emission (and prevention of sufficient formation of same to attract a stepped-leader) relies on theories that you would find can work in the bathtub but have no relevance at all to lightning, for you see my friend, there are indeed great differences in the way electricity behaves when it has exponential power behind it. It would take thousands of Charge-Transfer-Systems (the ESE models) in a single location to effect a measurable favoritism of attracting or avoiding a single lightning charge. Yet in the bathtub (which is a very accurate example of how water does not behave the same as in the ocean) sized experiments, pointed-tip objects do attract charges. Too bad lightning doesn't actually behave that way, it would fit those classroom models so nicely!

A good example of draining a pitifully weak thunderstorm cloud without experiencing an actual strike, is the St Elmo's fire (and lesser but physically noticeable yellow air-coloring and even wet skin hair standing up) that happen on sailboats in a storm. I have experienced the latter several times, and while lightning struck the water close around, did not strike the mast by great luck we could say. It was NOT a grounded sail boat (Morgan, Out Island-41) and the potential from chainplates to waterline would have been explosive had we been struck. There is no model that I am aware of in thirty years of reading about this, that explains why a 65' aluminum (but ungrounded) mast alone on the water in the middle of a thunderstorm is not struck. And the boat was never struck in countless exposure to such storms. I add this just to allude to the fact that while we have learned a lot more about lightning in the last twenty years than we knew in all of history up to that time, much remains a mystery. I still find myself out on the water in thunderstorms, and also operate a communications station without securing during storms, so it is certainly a field that I have a vested interest in learning more about. I probably learned more from your brilliant explanations of lightning protection experience than any fifty other people I have talked with. And although he lives in a area practically void of lightning, I include Richard Clark in this category also because he is so well versed in the annals of common mode, transmission theory, and a very well read liberal indeed. ;-)

In case you're wondering, I have indeed added blunt-tipped lightning rods to the roofs of my residence. But I am also quite sure that the safety factor of impalement-avoidance is much more likely than the chances that my roof will ever be struck, with or without lightning rods. As there are now only four of the twelve pines which surround my home that have *not* been struck, somehow the odds seem to be approaching me! Four HF antenna systems are suspended or attached to three of those "virgin" trees ;-)

Only if the bulbs are in American cars.

Hi Gary,

The filament lightbulb lifetime increases at the inverse 12th power of its reduction from the "suggested" operating voltage. This curve actually holds only for about the first 5 to 10% of voltage depression (otherwise they would last forever at half power). This is one reason to buy industrial bulbs (rated at 130V).

The benefit of LEDs is lowered current consumption for the same brightness (which I will warn is another one of those tricks of the brain). This is also a deficit for turn signals because it has a tendency to change the tempo of the flashing which can be mistaken as multiplexing. :-) The suggested fix is placing a resistor in parallel to return the circuit current demand to the original level.

Reg, G4FGQ wrote:
"A few years back I opened the highish-level kitchen microwave oven door and felt what seemed to be a warm breeze of air on my face and especially around my eyes."

I coincidentally happened across a couple of related stories. First, Louis N.Ridenour wrote in "Radar System Engineering":
"A British Technical Mission arrived in Washington in September 1940 and mutual disclosures were made of British and American accomplishments in radar up to that time." Seems the British had invented a magnetron. America thought it important. On board my ship during WW-2, we kept the spare for our Raytheon SO radar in the ship`s safe!

Second is from IEEE`s June 2003 edition of "The Institute":
"In 1946, Percy Spencer, an engineer and inventor who held more than 120 patents, was conducting radar-related research for Raytheon Corp. While testing a new type of vacuum tube - the magnetron - he noticed that the chocolate bar he had been carrying in his pocket had melted. Intrigued, Spencer began conducting more experiments. He watched popcorn "pop" and bounce around the room when he held a bag of uncooked kernals up to the tube. Next, Spencer observed a raw egg placed next to the magnetron explode from the pressiure that had built up inside.

Spencer concluded that each of the items had "cooked" when exposed to low density microwave energy emitted by the magnetron. Raytheon engineers quickly adapted his discovery, and the first commercial microwave oven, the "Radarange" began to move into household kutchens the following year.

The Satellite industry tracks Satellites by monitoring a beacon
transmitter on the Satellite and moving the dish very slightly in a
predetermined pattern at prescribed intervals to keep the antenna
peaked. Depending on the speed of the motors and other factors, you can
track an object with an RF source as it moved fairly quickly across the
sky with this simple method.

If you do the calcs you will find the exposure level for a 2-meter HT
held close to the head is probably an order or two magnatitudes higher
than you can get from standing 100 feet from an array running the
legal limit. The array would have far more than the allowable limit.

Now they say it's the exposure time, but most of the hams I see using
HTs make transmissions long enough for the HT to get down right hot.

OTOH you can stand within a few feet of a 180 meter dipole running the
legal limit and still be well within the safe limits.

I'm running a stacked pair of 12s on 144 MHz at 130 feet. The maximum
I can run into those antennas is 380 watts. That is measured at the
antennas.

Hi Jack,

"It is quite obvious from these plots
that the experimentally determined electric field
strength is less than the "simple-minded" V/d value."

Interesting brush-off so early in the paper begs for real editorial control. As very few would experience lighting sourced from a grid of wire 5M overhead this paper seems an example of the "laboratory factor" it set out to examine and yields a paper confined to laboratory arcana. All fine and well, but what is the point?

"There is an urgent need for detailed theoretical
modelling which can quantify the space charge
effects around air terminals, particularly in
relation to upleader development."

Which seems at odds with your statement:
On Fri, 7 Jan 2005 01:17:07 -0500, "Jack Painter" <223bthp@cox.net>
wrote:

Yes, let's have more technical discussion and less name-calling, please.

There seem to be three observations that need to be understood.

1. The electric field gradient near a sharp point is greater than the field gradient near a blunt point. This is basic physics and should be completely beyond dispute. But that is the field gradient IMMEDIATELY LOCAL to the point... and that's not what lightning protection is about.

The whole point of lightning protection is to make a strike attach specifically to the installed "terminal' and lightning conductor, and not to any other part of the structure that the installation is aiming to protect.

So what we want to know is: when a lightning probe leader (the column of ionized air coming down from the cloud) approaches the structure, how does the lightning protection terminal attract it from a distance of many feet away? How does it say "Hey, come over here"?

2. According to Moore et al (the source of the USA Today story that Jack quoted earlier) a very high field gradient immediately local to tip may actually be counter-productive, because it can produce corona discharge which *reduces* the field gradient at a greater distance; and this may make the probe leader attach somewhere else where there isn't a corona.

At least, that's my reading of Moore's papers (following the trail of references from the USA Today page, back to the institute in NM where Moore and colleagues are based). They have a lightning observatory on top of a mountain, but there only seem to be three short guyed masts with a different type of terminal on each. Instruments in a small underground lab collect the data from lightning strikes.

Going back through the paper trail, they have been operating this facility for more than 10 years, and occasionally produce a paper to one of the lightning-related journals accompanied by a press release (the latest of which was picked up by USA Today). However, lightning only strikes when it feels like it, so the statistical data only build up very slowly... and if they change the setup on the mountain-top, they'd effectively have to start again.

Moore's conjecture that you can make the tip of the terminal *too* sharp is interesting, but his type of "live lightning" experiment doesn't provide any specific backup for what he's saying. It only produces the raw observations that he's trying to explain.

Then there is:
3. The paper that Jack quotes above, which reports experiments in a large 'lightning lab'. The experimental setup is big enough to investigate effects over a range of several feet, so controlled lab experiments could bring us a lot closer to the basic physics.

Unfortunately these particular experiments don't seem to help. Same as with Moore's work, the experiments are heavily biased towards commercially available lightning terminals which (rather like TV antennas) come in a variety of weird and wonderful shapes. The performance of commercial off-the-shelf terminals may be what the lightning protection industry wants to hear about, but these complex shapes (with their faint odor of snake oil) make it impossible to understand what's happening at a basic level.

So it's still wide open for speculation and experiments. Moore's conjecture - that you *don't* want a corona discharge, so the optimum tip radius is the one that produces the highest possible field gradient but *without* inducing corona - looks attractive, but as yet it doesn't have much theoretical or laboratory backup.

We have to be missing something here in this discussion. There has to be a whole range of scientific papers, in much more respectable physics journals that are far removed from the lightning industry, that we're not aware of.

I would think that lightning protection should begin with the safe equalization of charges. If one could prevent localization of charge, there wouldn't be anything to discharge. Failing that, if one could provide a controlled discharge mechanism, that drains charge without a massive discharge channel, that would also be good. Failing that, you fall back to a point <g> defense; first dissuading the creation of a conductive channel to the protected area, or, failing at that, providing a specific, perhaps sacrificial path for the massive discharge.

The first methods, involving charge management, might be effected by controlling the conductivity of the air. Chemical and mechanical methods seem difficult to deploy and might not be able to affect sufficient volume. I wonder if conductive air volumes, or specific channels, might be created by RF stimulation? Might it be possible to map the atmospheric charge, and through an array of steerable microwave exciters, create specific conductive paths for the relatively safe dissipation of localized charge? I wonder if the HAARP has investigated lightning control possibilities?

306. Does a j pole need grounding and/or a balun?

Newsgroup: rec.radio.amateur.antenna

I have been reading alot on different designs and have read contradictory information on this. Does nayone here have an opinion?

Also, when building a j-pole, could I run the wire inside the tube. (Regular jacketed copper wire) to the bottom of the tube to a pl connector? Or would this mess up the impedance?

Forget the scissors and use an Exacto knife on the center insulation.

Oh, how we all wish! But think what that implies...

>If one could prevent localization of charge, there wouldn't be anything
>to discharge.

That would require control over the weather - and again, oh how we all wish!

>Failing that, if one could provide a controlled discharge mechanism,
>that drains charge without a massive discharge channel, that would also
>be good.

But again, we don't know how to do that. Starting from a weakly ionized probe leader, lightning has a huge positive feedback mechanism. Once it has started to go, it'll go all the way!

>Failing that, you fall back to a point <g> defense; first dissuading
>the creation of a conductive channel to the protected area,

If an ionized leader has made it all the way down from the cloud into the region of the protected area, we don't know any way to tell it "Wrong Way. Not In My Back Yard".

If the leader has come so close, you absolutely cannot stop what's probably going to happen next. All you can do is do is to design the protection system to make the best of it.

>or, failing at that, providing a specific, perhaps sacrificial path for
>the massive discharge.
>
At last, we've come down to earth. All that lightning protection can realistically aim to do is providing a specific path. The whole aim of lightning protection is to provide a safe discharge path *past* the structure that's being protected, as opposed to a damaging path *through* the structure.

A "sacrificial" path is not an option to design for. The lightning conductor *must* hang in there for the whole duration of the stroke(s), or else protection will be lost before it's all over.

To keep the original discussion in perspective, all this stuff about terminals at the top end of the conductor is about trying to achieve some kind of "come here" effect in literally the final few feet of the

entire lightning path (or tens of feet, if we're really lucky) to make sure the leader attaches to the terminal and not somewhere else on the structure.

The well known and most reliable way to do that is to make the terminal higher than everything else, so it dominates the local electric field. But that's still no guarantee that a leader won't come wandering down at some distance off to the side, and then strike downward or even sideways from there.

Bottom line: it's absolutely vital to be realistic about what lightning protection can do - and also what it cannot do. A system designed out of hopes and dreams will be the wrong system.

> from the inside of 300 ohm ladder-line wire than from flat antenna wire?

Because more than half has been chopped out already. You can cut
the ladder-line at a place where there's no center insulation and
have one inch wire tails needing only a wire stripper. If you
need longer wire tails than that, you only need to cut out about
1/4" of center insulation with an Exacto knife to achieve two inch
wire tails.

Ok, I understand what you are saying. Moving the coax affects the
"impedance". How does one effectively "tune" then by shortenign or
lengthening the elements?

Maybe I did not explain properly. I use a coax switch to select either the FT-920 directly and thereby use the built in autotuner, or select an external manual tuner when I bypass the internal autotuner. This allows me to use either the built in autotuner, or the manual tuner, depending on the band. Most of the time the autotuner is just fine with the antenna I described. I don't understand why you thought I had 2 external tuners? Anyway, I hope this clears that up.

Good morning, Jack.

Well, that's not entirely true I don't think ... it's probably true
enough when referring to a physically-short antenna that you're trying
to extend well beyond its range, but I have a 160-meter inverted vee
fed with an open wire line that works very, very well on 160 through
10 (haven't tried it on 6 yet because my manual tuner won't go that
far).

Thanks for the eham.net link, I'll check it out.

What has higher gain?

A vertical dipole or a a 5/8 lamda vertical?

Is there any difference in gain between a center fed dipole or a 1/4
lamda matching stub feeding an end fed dipole such as the J-Pole?

I have owned a few different autotuners. They are a great convenience, but not without some cost in performance. The reviews I have seen on the efficiency of autotuners can be depressing. In fact, I have seen insertion loss figures as high as 65% on some bands and some crazy impedances.
I think this is due to the use of toroids and fixed capacitors in autotuners. A good efficient tuner usually has high Q air inductors and well made variables. Maybe that explains it, maybe not. However, they sure do work nice! I used an old SGC at the feedpoint of a 30 foot homebrew vertical. It was a kicker on all bands from 160 through 6 meters! Now, that of course is my own anecdotal experience, and the antenna may have been inefficient as hell, but it got me on the air and I got out real well. I have also used autouners on random wires and such, and again they work well. But expect to lose a fair amount of power.

"Time-multiplexed" means that they're turned on in sequence, without all being on at once. That would be as opposed to simply pulse modulated all at once.

My guess is that they're pulse modulated to provide easy and efficient control of the brightness, and possibly compensation for voltage and/or temperature. If they're time-multiplexed as well, that would even out the total current drain rather than its being in the form of big current pulses.

Are they really time-multiplexed, or are they all pulsed at once?

As I understand it, a J-pole is derived from nothing but an inverted Zeppelin-antenna. That makes the feedpoint a balanced one and you need a balun or at least a choke. But as a Zepp-antenna it does not need any ground just like ordinary dipoles don't. But if you ground a J-pole the ground needs to be exactly in the middle of the short in the feed line. For practical reasons most J-poles are not constructed this way.

I have antennas, towers, tall trees, and power poles on my
property. Lightning chose to strike a five foot tall Live
Oak tree, killing half of it. The other half is still alive.

A 5/8 WL vertical *with an excellent ground plane* has about
3 dB gain over a vertical 1/2WL dipole.

> Is there any difference in gain between a center fed dipole or a 1/4
> lamda matching stub feeding an end fed dipole such as the J-Pole?

Both radiating portions are 1/2WL so they have about the
same gain.

Hi,

Well, I receive some answers, found others on the Internet, all is now written in my 3 pages (see ref below).

The big picture:
There is surely no influence of HV power lines at 300m away. And probably no QRM on HF bands at that distance either. But will know more about HF consequences when will be on the air in the field...;-). I retain the idea of Cecil on 40m.

No study can confirm the direct relation between some leukemia and HV power lines located to say <100m from houses. There are leukemia observed with radiation equivalent to a exposure to an HV power line < 75m away.
On the other hand, companies recognize that beneath pylons (25m away) there is a risk for the health (and some electrical devices) due to the strong current and voltages, far higher than the current limits (see end p3 of my text,under guidelines) which are thermselves, already 50 or 100x higher to the values potentially at risk for security reasons.
But I don't see how we could contact a leukemia without a durable exposition. It doesn't come eating your familiar food and cookies... or half the population 'd be contaminated. As around the concerned spots studied by IRPA there is no other powerful sources of emission excepted these sad pylons...
At last, the risk is not black or white depending on the distance or the radiation level. All this is progressive and hard to define, hence the deep fog envelopping all studies.
WHO is currently studying the problem more deeply.

More info of my site with many links and some books to read.

The most trivial case of binary time multiplexing would be a
single LED being turned on for a logic 'one' and off for a logic
'zero'. That "binary time multiplexing" concept is a carry over
from 40 years as a digital engineer, 13 of them at Intel.

> Are they really time-multiplexed, or are they all pulsed at once?

It appeared that they were all pulsed at once. Perhaps I should
have used the word "pulsed" to avoid confusion in the RF analog
(non-digital) world.

Yeah, digicats have their own language. In analog parlance, multiplexing basically means sharing. As in telephony, where you share one line among many users by connecting each to the line for a short time in sequence (time division multiplexing or TDMA - time division multiple access), breaking the spectrum into pieces and giving each user his own channel (frequency domain multiplexing), or more complex methods such as spread spectrum code domain multiplexing, or CDMA (code division multiple access). There's no sharing when there's only one user, channel, or LED involved, so no multiplexing. Except, I guess, for digital types who can share an LED between a 1 and a 0.

Just out of curiosity, what does your revered IEEE Dictionary have to say about it?

328. Want Maxcom Antenna Matcher

Newsgroup: rec.radio.amateur.antenna
Date: 2005-01-07 17:32:05 UTC
From: Skipp knows what the Maxcom is <skipp025@yahoo.com>
Message-ID: <crmh2l$h8a$1@skeeter.ucdavis.edu>
Source record: 84166
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.swap,rec.radio.swap

Hello there,

Yes, I know what's inside it and how it works... but I'd still like to find a Maxcom Antenna Matcher.

If you have a Maxcom Matcher you'd like to sell, please Email me direct at: skipp025@yahoo.com

It can even be in most any condition...

Thanks for looking at this want ad.

cheers
skipp

Moving the coax up or down only changes the impedance.
there is a sweet spot of 52 ohms between the lower end 700 ohms and
the upper end 300 ohms of the impedance range.

Tuning for a center frequency is most easily accomplished by
installing a brass machine screw in the pipe caps after you shorten
the antenna and stub slightly to give you tuning room.

I fully understand what I implied; this would be a technique well beyond our current capabilities. OTOH, it would be a grand concept. And we wouldn't have to "control the weather", just finesse one part of it, for a short time, in a very local region, so it might be applicable to protecting extremely valuable items and events, like maybe a shuttle launch or landing.

You don't know how and I don't know how, but that's a long way from knowing that it's impossible. And I won't concede that there's no mechanism to modulate a discharge.

Sacrificial was a bad term; I didn't mean to imply that it wouldn't be durable, just that it would be the path to take the hit and protect the rest of the local area.

I HOPE I'm not there when it hits, and you're DREAMING if you think I'll volunteer to hold the rod. That's being REALISTIC on my part. Seriously, if all you can propose is a thick, conductive pole, then you are entering the fight at your last line of defense. Think about the whole problem, not just optimizing the existing solution.

And BTW, what would be so bad about having some way to create a conductive channel from the charge to a place of YOUR choice? Even that modest goal could vastly expand the "cone of protection" that existing masts provide. Imagine being able to initiate safe cloud-to-cloud discharges. Imagine being able to direct all charge for a one-mile radius to discharge (even violently) to a designated lightning rod. One rod could protect an entire building; several rods could protect an entire large airport. My speculation about selection paths of ionization by RF excitation was just groping toward one way to create those channels, and HAARP naturally came to mind.

331. Re: Does a j pole need grounding and/or a balun?

Newsgroup: rec.radio.amateur.antenna
Date: 2005-01-07 17:50:05 UTC
From: raiar@bbs.galilei.com.nospam
Message-ID: <41dec8ff.1935086359@news.galilei.com>
Source record: 84169

A J-Pole is a 1/2 wave vertical antenna, that sits on TOP of a U
shaped 1/4 wave matching section.
During construction, the 1/2 wave vertical element AND ONE of the 1/4
wave legs of the Transformer are constructed of the same piece of
tubing. Thus the J appearance and name.

RF is invisible to whatever lies below the Horizontal Member, so
whether the mast is grounded or not would have no impact on the
J-Poles performance. However, the shield MUST be grounded for obvious
reasons.

It is Normal and Proper to RUN the COAX up the center of the mast,
INSIDE the Antenna and EXIT the vertical element at the Horizontal
Member.
If you don't, THEN you will need to stop stray RF that runs along the
coax and/or use a Balun.

When you connect your COAX to the J-Pole:
If it is a MonoBand J-Pole, run the center conductor to the STUB,
leaving the sheild jacket intact up to within about 1/2 inch of the
stub. Then run a wire from the shield horizontal to the horizontal
member and affix this to the vertical.
If it is a Multi-Band J-Pole, the center conductor should be connected
to the Vertical Element and a wire from the shield runs horizontal
over to the stub.

Although a J-Pole will work with the coax connected either way. On
MonoBand J-Poles, having the center conductor going to the Stub
reduces the noise level slightly. It can make a difference when you
are trying to pull in QRP stations.

Using 3 or 4 1/8th wave wires, like a capacity hat, protruding outward
on the top of the vertical element will give the same noise reducing
effect.

Source record: 84171

Cecil,

Here's the deal.

I will assume the low intensity tail light and the high intensity brake light share the same LEDs. In a typical system there will be 10's to even 100's of LEDs. The required light output from the tail light function and brake light function is quite different. I have seen numbers from ranging from 7:1 up to 15:1. Let's say that the brake light requires 10X the output required from the tail light.

Contrary to what was posted earlier in this thread, the light output from LEDs is roughly linear with forward drive current over several orders of magnitude. This is true up to nearly the point where the device explodes from overheating.

So why not just change the DC current to get the varying output required?

The problem is device matching. As you well know all semiconductor devices are subject to significant performance variation depending on exact process conditions, materials, phase of the moon, or whatever. LEDs are typically specified at one nominal current, with a nominal light output.

When used at the nominal conditions a batch of LEDs can be selected to match light output performance so that no obvious visual artifacts appear. However, if these same matched LEDs are driven at significantly different conditions, the light output will have wider variation, perhaps detectable to the ordinary observer.

Therefore the recommended method for reducing light intensity from a matched array of LEDs is to operate at nominal electrical conditions, but at a reduced duty cycle.

I do not know the details of the vehicle you observed, but it is likely that the brake light function uses DC or a high duty cycle pulse, while the tail light uses a low duty cycle pulsed activation.

There are other issues such as temperature variations and dealing with non-functioning LEDs, but that is enough for now.

Jack Painter wrote:
"Your example of lightning was the opposite, and very rare, from the normal occurance of lightning, which is not positively charged."

I won`t predict nor defend either polarity of charge in an overhead cloud. In either case it will attract the opposite charge beneath.

In my example, I chose positive for the cloud because now it is popular to characterize electrons as the mobile electrical particle. My formal education was that regardless of what electrons do, current flows from plus to minus. In my hypothesis, I chose to characterize what charges were doing in the earth and other conductors. Electrons are considered mobile due to extremely small mass, so I chose them as the moving charge.

Effects of lightning are identical regardless of polarity or direction of travel for practical purposes. Significant factors in lightning protection are the maximum voltage reached across a protected device and the current through it. We can`t do anything about the millions of volts and the thousands of amps behind a lightning strike. We can put high impedance between the strike and our protected people and products and we can clamp the volts across them.

I`m sure that polarity makes no difference, one, the other, or both. For sure you must be prepared for both because lightning is a transient. In its start and stop, it generates powerful alternating components which include the entire radio spectrum.

Arc gaps are effective protectors which have dependable breakdown voltages for a given atmosphere, temperature, pressure, presence or absence of triggering radiation, etc. Breakdown voltage is proportional to gap width for given conditions. Electrode shape is significant in the striking (breakdown) voltage. Blunt electrodes require significantly more volts to arc across than do needle points. Anyone in the TV business knows that corona discharge from the high-voltage circuit occurs from a sharp point. Once a corona is producced from a point, conductance extends as far as the corona reaches.

I agree that charged air arrives in advance of a thunderstorm, whatever the polarity of charges may be. I`ve spent many years in broadcast stations and observed the storms. Before the storm arrives, tower guy insulators flash across from charges picked up by the guywire segments out of thin air.

On arrival, a bolt from the sky hits a tower or towers. Maybe it`s the reverse that occurs. It makes no difference. The station and its

equipment are protected by the tall towers. In lightning rods, more is better. All the stations in my experience used multitower arrays. None ever had significant lightning damage. Much of the time they were operating 24-7 and they might be dropped from the air for an instant due to a temporary overload caused by the lightning strike.

The medium wave stations I worked in had blunt lightning discharge electrodes. Lowest breakdown voltage wasn`t a requirement. The final amplifiers used vacuum tubes and were sturdy. The tower base insulators all had ball gaps side by side across them. Precipitation fell right through to have little effect on their striking voltage. Tower balls never fire anyway. It`s always the Faraday screen between the primary and secondary of the tower coupling transformer thet takes the lightning hit. The impedance and striking voltage are higher at that circuit point. The screen is heavy and easily withstands lightning strikes.

The shortwave stations I`ve worked in, all had arc gaps at the feedpoint of their parallel 600-ohm transmission lines. These were adjusted so that they just had 10 thousandths of an inch more than the minimum spacing required to prevent breakdown on full 100 KW carrier output with 100% modulation. These gap electrodes were consstructed like the letter V turned so one side was horizontal and the pointed ends of the V`s pointed to each other. The upward slope of the arc gap meant that heated air in the gap would rise increasing the arc distance so it might self-extinguish. We never had any lightning damage in the short wave plant with its dozens of antennas, lines and transmitters.

Sharp points lower breakdown voltage. In a situation where charge across a capacitance, auch as between a cloud and the earth, has increased to the breakdown value, it happens where there there is a sharp point in the neighborhood of the charge concentration.

Blunt electrodes require higher potential to flash over than sharp electrodes. For given electrodes in a controlled environment, the distance between electrodes can be calibrated in volts required to jump the gap.

Arc gaps are spaced to clamp the maximum voltage across them to a safe value. CRC`s "Handbook of Chemistry and Physics has a table of the voltages for blunt and sharp electrodes.

Best regards, Richard Harrison, KB5WZI

NEC anylisis I've done doesn't not show that to be true. A j-pole directly connected at its base to a conductive mast will increase higher takeoff angles. The worst case is with mast lengths of even ï¿½-wavelengths. With mast lengths of odd ï¿½-wavelengths produce less, but, in ether case connecting a j-pole to a conductive mast will increase high angle radiation patterns.

What about the Hustler antenna instructions which provide the "correct lengths" for cutting radials? Moreover they need not be "buried 2 inches" in the ground but can safely remain on the ground once grass growth effectively buries them. Also DX Engineering www.dxengineering.com has ground radials for sale which are "pre-cut to length". I assume they know what they are doing. Force 12 also recommends using "tuned radials" with their line of vertical antennas. I assume they too know more about antennas then I do.

I researched this topic before installing my 5-BTV and tuned radials were always recommended. If length means nothing I could have gone with 6 inch radials if I followed your logic...eh? My 5-BTV installation with 72 "tuned" radials at this page

1. http://www.ad5th.com/5-BTV.html

I am getting great reports so far but have only been on the air at this qth for a couple weeks. A new AL-80B arrives in 3 days which should improve my signal greatly. 73 / DX

Thanks for the box cutter suggestion, Bob!

Perhaps I can fashion a metal stamp for this sort of thing. Just a U-shaped piece of lawn mower blade or something like that. A good whack with a mallet would cut out an appropriate chunk neatly and consistently. But I'll use the box cutter and ladder-line until volume gets really heavy.

Tuned radials are necessary and appropriate when the radials are
installed well above earth-ground level. When the antenna is mounted
up at a significant height, there's very little coupling between the
radials and ground, and the radials must be tuned in order to present
a low impedance on the frequencies of interest. Once tuned, each
radial presents a low-loss current path, and only a small number of
such radials are required.

When the radials are laid on the ground, buried, or placed a short
distance above the ground, matters are very different. There is a
great deal of capacitive coupling between the radials and the soil,
and the soil also presents a (resistive and rather lossy) path for the
current flow. As a result, two things are different:

- The coupling to the soil de-tunes the radials and greatly lowers
their Q. They no longer serve as a resonant system, and cutting
them to a tuned length is no longer essential.

- A much larger number of radials is necessary, in order to limit the
losses which occur when the return current flows through the soil.

So... in an elevated-antenna situation, as few as three or four
radials can give you low losses, but the radials must be tuned. For a
ground-mounted vertical, you need many more radials (dozens, and some
people prefer over 100), but they don't need to be tuned, and there's
not much performance difference to gain once the radials are at least
about an eighth of a wavelength.

>I researched this topic before installing my 5-BTV and tuned radials were
>always recommended.

For elevated antennas, that's true. For ground-mounted antennas,
tuning is simply unnecessary.

Take a look at http://www.cebik.com/gr.html which shows some antenna
modelling and graphs for vertical antennas with ground-mounted
radials. The chart of "Ground Radial Test 2" is an interesting one.
It shows that there's only a very modest difference in performance
(less than half of a dB!) between a 64-radial system using tuned

quarter-wavelength radials, and a 64-radial system using radials which
are only .15 wavelength long.

> If length means nothing I could have gone with 6 inch
>radials if I followed your logic...eh?

It is not true that "length means nothing". 6-inch radials are too
short to provide adequate coupling to the soil.

It *is* true that "length is not critical".

That's good news.

The bad news is that you could have used non-tuned radials, and saved
yourself some bother and perhaps some money (used somewhat shorter
lengths of wire), and gotten equally-good reports.

You didn't hurt yourself by tuning the radials. You just invested
some effort (and perhaps some money) unnecessarily.

Thanks very much, Gene, for that information. I only observed
the pulsed taillight function and not the braking function so
the above explanation didn't occur to me. Makes a lot of sense
now. Thanks again.

Possible the controversy is in your mind Charlie.

The velocity factor using wires buried under ground is a fraction of
the velocity factor in air or free space. Hence if you are hell bent
on having resonance in your buried radial system (which in this
application does nothing to improve system efficiency) they need be a
whole lot shorter than the length = 234/F that is used for elevated
radial systems.

So, if coax is kept inside the tubing, there is no stray rf and
therefore a choke or balun is not needed?

Are you saying the shield must be grounded to a surge supressor to
prevent lightening stikes?

My ideas was to run the wire inside and even make the coaxle
connections inside the tubing with wire terminals and screws, so as to
keep everything neat and weath proof.

What if you used a non insulated pvc type pipe to connect the stub and
verticle element?

You may want to consider building a stainless steel fractal antenna. it is purported to have more positive characteristics than even the best CB antennas.

The fact that you can weld will save a lot of bending.

A long time ago, there was some (theoretical at least) effort to see
whether UV lasers could be used to create an ionized channel over a
long distance. Something like that might do the job. OTOH a
rainstorm is generally pretty opaque to UV.

Teh RF excitation has already been tried -- I think someone has a
patent on it. One problem with it is that where there is lightning
there tends to be wind, so that the ionized air is blown away faster
than it can be generated.

Ah, binary again. I disagree with all entries or I disagree with none, with no other possibilities. Spoken like a true digital engineer.

Indeed, I often disagree with that book, and don't feel that it does a very good job of reflecting usage among working engineers. But apparently on this issue I do agree with it -- a possibility only in my analog world but seemingly not in your digital one.

Hi Guys,

One has to wonder about the consequence of double jeopardy standing
beneath that antenna (HAARP experiment) or holding the laser.

Think insurance covers this?

Supply shop foreman (perplexed):
"Another laser? What happened to the last one?"

Tech (smoke curling up from clothes):
"ummmm, burned out real quick-like. Could you hurry? They say
more rain is on the way!"

From: Mike Coslo <mcoslo@adelphia.net>
Message-ID: <9r6dnVKltefNrELcRVn-uA@adelphia.com>
Source record: 84095

I'm using a homebrew dipole at the moment. It is a fairly typical one, with coax going to a 4:1 balun. Short side 40 some feet, and ~135 feet total. Roughly What I am curious about is that 80 meter operation is pretty good, 40 meters is good also, but on 20 meters it, for lack of a better word, sucks.

Is the OCF multi-band antenna a dog on 20 meters?

You can try one of thouse 'automatic' wire stripper things , radioshack
used to sell them sure other places must perhaps sears and junk
stores the goodones like i got cost 20$$usd, seen cheepies at flea
mkts and such for like $5bucks

they claim to strip anything it's mouth on mine is 3" i got the model
designed to also strip ribbon cable but the smaller ones will strip tv
antenna style no trouble it will also strip telco flat 'satin' cable
either silver only or silver and wires all w/one squeeze! wow

it also strips the wire w/o nicking the copper and you don't have to
set it for diff ga , just squeeze handle seems unbelieavlbe looks
cheep but so far it worked for me,

if you use it alot buy a few spare blades onece they go dull it will do
bad things

For what it's worth, I'll add my voice to Dave's and Danny's. The change in velocity factor Danny speaks of is on the order of a factor of 5 for ordinary soil. That is, a quarter wavelength under the ground is about 1/5 the physical length of a quarter wavelength in free space or well above the ground. So if you did need to "tune" buried radials for any reason, you'd have to make them about 1/20 of a free space quarter wavelength. And the "tuning" would be extremely broad because of the loss.

To amplify what Dave said, the current on an elevated or free space radial has nearly the same distribution as on a dipole half -- it's maximum at the feedpoint and drops to zero at the end, following a nearly sine shaped curve. When buried in the lossy ground, it instead decays in a more-or-less exponential fashion. In some cases there are some remnants of the free-space distribution, but they're very muted. So basically, the current just fades out as you get farther and farther from the feedpoint. At the point where the current has dropped to a low value, you can cut the radial with no significant effect. This is very much different from the behavior above ground.

I'm not surprised to find technically inaccurate material coming from antenna manufacturers. Although they might know how to build antennas, and certainly how to sell them, they often don't have any great depth of knowledge of fundamental principles. (In fact, a lack of knowledge of fundamental principles is often an advantage in the selling area, because it gives them an excuse for making claims of impossible performance, and the invention of non-existent phenomena to explain it.) I recall many years ago contacting a major manufacturer of coaxial cable about a theoretical matter, and found that they knew nothing at all about how transmission lines worked. They were experts at extruding polyethylene and PVC and at weaving fine copper wire, and nothing else.

Richard,
Thanks. I always find your comments about scientific material interesting.
There is some monumental evidence accumulating to contest ESE/CTS, and this

begs the question that if there is such a political fight over preventing its presentation to the whole IEEE body for a vote, what are they so afraid of? Russian scientists have now been commissioned to find (contrary to all other studies) that the principle works. Avoiding the comments about streamers in the referenced paper though, my point really was that they arrived at a statistical average they may have been looking for, but attempts to remove the laboratory principle appeared honest to me (and to others). Your opinion there is important, at least to me.

Baloney. By this definition, OOK Morse is a "time-multiplexed"
system, eh?

Why not just Google this: define: multiplexing

Then try this: define: time multiplexed. And the answer is, "Huh?"

What you mean is that the LEDs are pulsed at some rate and/or duty
cycle. I wouldn't call this, "multiplexing."

Hi Jack,

Well, when I look at these tempests in a teapot, I reduce things
myself.

For instance, this distinction between a sharp point on a rod and a
blunt point on a rod. Nature hardly takes the time in a lightning
strike to be so particular. This is so multivariate a problem that no
single variable is going to be a determiner at this rather fussy level
of detail.

The reduction consists of the logic in the extreme. We have a blunt
rod, we have a sharp rod. It is purported (or I have read the
controversy completely wrong) that this makes a difference, somehow.
We put those on a yet blunter rod (a tower); or with a yet blunter rod
(another tower) nearby (in the scale of miles transit, nearby by
hundreds of yards/meters/feet/inches/cm is very proximal) and yet such
neighbors are not the choice of the stroke (or they are and this
upsets the catalogue of evidence).

Hence the reductio ad absurdum is that blunt points are significant,
but not too significant.

All that aside - I do not dismiss the topic entirely. It offers
something I have found in my own work. The near field area to a
monopole:
http://home.comcast.net/~kb7qhc/antennas/Fields/Vertical/index.htm
displays a very marked disturbance above it. The introduction of a
metal pole into space distorts it far beyond the borders of the
graphic pointed to. In a sense, it acts like (in my imagination) the
vertex of a energy well; or at greater scales, a dimple in the fabric
of the ï¿½ther. Such analogies and illustrations are intriguing, but
not conclusive of anything but how to intellectually amuse while
monkeying with numbers.

Again, the high insertion loss is with autotuners into a huge mismatch
on some bands..seems like the higher bands from what I have read.
I don't know this for a fact, only what I read in some reviews along
the way. I think I saw a QST product review or 2 that spec'd this
loss.
The 65% was worse case senario. But the insertion loss was always
higher than a good manual tuner.

That's nothing real new. Yes, is air dielectric and slightly less lossy
than regular foam dielectric heliax. Since you described the outer
conductor as aluminum, I suspect it is 75 ohm cable.... but not
necessarily. There should be info printed onto the outer plastic jacket
material mthat would help in specifically identifying that cable.

I just want to thank all of you for your kindness and speediness in pointing out my error as a new vertical antenna user. I am glad several of you had a laugh on me for burying tuned radials. Thank you for your kindness and courtesy. Hope to catch each and every one of you on the bands. I am grateful for the tact and diplomacy that many of you showed me. True Ham Spirit at it's best.

Based on what I have been told by the gentlemen in this great group I could have used much shorter radials than any "tuned length". If that is right then I have achieved a much more effective radial system then what I would have had I not erred. Is this right? In other words I have more wire in the ground then I need..right? Now if that is so..does that hurt or help

Source record: 84112

Nobody's laughing at you -- it's a topic that's very poorly understood.

Here's how it works with buried radials. . .

It never hurts to make them longer. But beyond some distance, it doesn't help appreciably -- if the current on a radial has dropped to a negligible value at its end, extending it won't do anything.

What is this distance? Well, like so many other things, the only really honest answer is that it depends. As it turns out, the current fades more rapidly if you have only a few radials. So if you only have a few, it doesn't help to make them super long. If you have a lot (say, 60 or more), increasing the length has more effect -- but your system will already be so efficient that it won't make much difference.

The classic set of measurements of various ground systems was published in 1937 as "Ground Systems as a Factor in Antenna Efficiency" by Brown, Lewis, and Epstein. Their paper has many graphs of the effectiveness of various combinations of radial lengths and number of radials for various vertical heights -- for the particular ground at the place of their experiments, the characteristics of which weren't recorded. Their data have been interpreted and reorganized countless times and in countless ways -- a web search should bring you a lot of hits. But some rules of thumb (and only rules of thumb) for amateurs(*) emerge:

1. There's not much point in making radials much longer than a free-space quarter wavelength or so.

2. Increasing the number of radials from 16 to 120 or more will probably net you less than a couple of dB. That might be worth it to you, it might not.

These assume more-or-less average soil. If your soil is very dry, you might benefit from more and/or longer radials.

And of course, there's no point in fussing over exact lengths. There's no need to even make them the same length. Put down what you can and don't worry about it. Putting in more won't hurt, nor will making them longer. But you're not likely to notice much difference between a big installation and a fairly simple one, unless your ground is extraordinarily poor.

Roy Lewallen, W7EL

(*) An increase in field strength of a few percent is a worthwhile pursuit for AM broadcasters, because it increases the size of their audience and hence the value of their advertising. Small increments like

that are completely useless for amateurs, though, so our goals are
somewhat different. Keep that in mind when looking through various
analyses and recommendations, since most are oriented toward broadcasters.

In a "Hints and Kinks" book - I believe - or maybe it was an Antenna
Handbook from the ARRL - they described how to make a matching network to
take that sort of heliax to use for 50 ohm purposes.

Don't feel bad Charlie, we read the book. <G>

I would really suggest you consider purchasing the current edition of
the ARRL Antenna book. There is a whole chapter (3) devoted to the
effects of ground. You'll find in more reliable information in that
book than you ever see in antenna manufacturers' statements and
claims.

Oh, yes when it comes to radials you can't have too much wire in the
ground, but you can hit the wall of diminishing returns.

It's a common misconception that the use of disks or foamed dielectric reduces loss because of reduced dielectric loss.

But, up to a frequency of somewhere around 1 - 10 GHz or so, that isn't true.

Below 1 - 10 GHz, the conductor skin effect loss is much greater than the dielectric loss of solid PE or PTFE (the common coax insulating materials), so further reduction of dielectric loss makes no appreciable difference.

BUT, going to disks or foamed dielectric does reduce the effective dielectric constant of the insulator. This results in the requirement of a larger diameter center conductor for the same Z0 and cable diameter. The cable does have lower loss, but because of the larger center conductor, not because of decreased dielectric loss.

Time Domain Multiplexing is where two or more signals share one data pipe. Under TDM each signal is allocated one domain. Each domain is sent in sequence. At the other end each domain is isolated and combined with other domains elements from the same source. i.e. a, b, c fragmented and sent as a1, b1 , c1, a2, b2, c2, a3, b3, c3 received and defragmented as a, b, c. Commonly used to sent telephone conversations and internet packets over copper wires and radio.

> Is the OCF multi-band antenna a dog on 20 meters?

EZNEC sez it has about 8 dBi maximum gain in an 8-lobed
pattern with 4 major lobes. It should be a pretty good
antenna in certain directions. If you are expecting good
20m broadside performance, which it has on 40m, then you
will be disappointed.

If the antenna is running N/S or E/W, the major lobes on
20m will roughly be in the NE, NW, SE, & SW directions in
a "cloverleaf" pattern.

You can see all this for yourself by downloading the free
demo version of EZNEC from http://www.eznec.com

A short mobile whip might have a feedpoint impedance of 2-j1500 ohms
yet an SGC-230 will load it just fine. 65% loss (or more) seems
understandable under those circumstances.

The fact that it is 75 ohm really doesn't bother me. I use 1inch dia Andrews hard line at the moment
for a 200 foot run but this other stuff was used for cable T.V. and computor stuff before they changed out to
fiberglass ,so I wondered if it was better than what I was using now and if so how much !
It does not have a plastic covering on it so no numbers are visible.
Regards
Art

Source record: 84117

Thanks Roy for a great yet concise answer to this matter. I misunderstood about tuned radials. I wish I would have done more then a cursory look at the matter. Basically all I saw was "tuned radials" and "you can't have too many". Had I read more I would have eventually seen that buried radials need not be tuned and that a 1/4 lambda would have been adequate. I have over 1300 ft of radials! Don't ask what my pre-cut "tuned radials" cost me!! I made sure I had plenty and now that this cabbage is boiled I am glad to see at least I did not do my station a disservice. Most importantly I learned something.I am not a new ham but am new to this vertical antenna scene.

I am aware of your reputation in this field Roy and I appreciate your warm, courteous and most of all informative replies. 73 / DX

Didn't you ever use an 8 to 1 *MULTIPLEXER* chip to change
parallel BAUDOT to serial BAUDOT? The parallel BAUDOT bits
are time-multiplexed into a serial bit stream by the
three clock bits. The first parallel bit is hard-wired to
yield a start pulse and the last two parallel bits are hard-
wired to yield a stop pulse. The center five parallel BAUDOT
bits are time-multiplexed from parallel to serial by five
states of the clock.

Again, you could do the same thing *without* using a coax switch. Simply run the FT920 direct to your external tuner and the output of the external tuner to the antenna. Use one tuner and put the other on bypass, or visa versa. This setup will allow you to use either tuner (or no tuner) on any band.

> I don't understand why you thought I had
>2 external tuners?

Never thought you did. Try reading that part again.

A little optimistic maybe....Normally, a dual 5/8 collinear
would give about 3 dbd. A single 5/8? As far as textbook
numbers,it's usually rated apprx 3.3 dbi vs the 2.1 dbi
for the 1/2 wave.
So only about a db or so...In modeling the 5/8 GP, using
sloping 5/8 wave radials gave the appx 3.1-3.3 dbi...
To get much more than that, you have to run two 5/8's elements.
The most I could get by using 5/8 radials sloped at a *real*
steep angle, was about 4.2 dbi. A normal dual 5/8 collinear
will do appx 5.1 dbi, but spacing can vary the gain.
MK

People keep saying that they use 4:1 or 9:1 baluns.
Often I can see no reason for this (such as when simply feeding a dipole
with coax, or on the output of an ATU).

I'm obviously missing the point. Why the impedance transformation?
Ian.

> I'm obviously missing the point. Why the impedance transformation?

==========

Nearly always there IS no point to be missed.

Reasoning seldom enters an argument.

Which of the infinite number of impedance ratios on one antenna are to be favoured?

Personally, I have never used a balun except of the choke variety which can be used between indeterminate impedances of any ratio to serve a recognisable purpose.

But the right to free speech must be held.

Hi Mike:

Did you miss my presentation on OFC dipoles awhile back at the club meeting?
The pattern on 20M is a clover leaf with gain with the main lobes at about
45 deg to the wire. We saw this at field day with the antennas broad side to
the west we had great signals into Maine but not so good into the Midwest.

If length means nothing I could have gone with 6 inch
> radials if I followed your logic...eh?

I thought my "logic" said "make them all as log as possible". If the manufacturs say cut radials to X length then lay them on the ground...then they need to go back to school. One rule of thumb is: Try to make the radial length at least equal to the heigth of the vertical. If the Hustler is 20' tall, make the radials at least 20' long and use lots of them. Having 50 radials 20' long is better than 8 radials 500' long etc.

Well, I could easily imagine a laser protected within a large conductive lightning rod. All you need is a 1/" hole in an otherwise well-shielded structure. Maybe a bit larger to allow for pointing, or you could put some optics safely outside the rod.

Regarding the RF excitation, I assumed that a single-point source would be dumb, because the best ionization path would be right back to YOU. But an array of exciters, electronically steered to create a sufficient power density at a focal point, is a lot smarter.

Again, I don't know if the technique would work, but an electronically steered (more like focusing) array would be one way to do it.

One poster said that the ionized channel might blow away in the wind. Maybe a quick system could "paint" an ionization channel fast enough. Maybe a system could detect and take advantage of leaders, to create a shorter path.

Those "Russian scientists" often seemed to come up with controversial and unrepeatable results. Old cold warriors wondered if the Russians were that much smarter or dumber. Then, in the 90's, we found that a lot of that weird stuff was internal political smoke and mirrors, more related to funding than science.

>So, if coax is kept inside the tubing, there is no stray rf and
>therefore a choke or balun is not needed?

Some stray RF somewhere, but not enough to worry about regarding the
antenna operation.
However, it is still a good idea to coil a few turns of the coax
before entering the shack.
>
>Are you saying the shield must be grounded to a surge supressor to
>prevent lightening stikes?
Not at all, the SHEILD should never go through a supressor.
For proper operation of ANY antenna, the sheild should be grounded.
For lightning protection the sheild should be grounded to an 8 foot
stake OUTSIDE and the center conductor run through a gas bottle also
grounded to the 8 foot stake outside. Actually, every piece of
equipment in the shack should be properly grounded.
>
>My ideas was to run the wire inside and even make the coaxle
>connections inside the tubing with wire terminals and screws, so as to
>keep everything neat and weath proof.
Sounds good on paper! But I have no idea if it would work, never
tried it. I do know this, with the shield grounded and the antenna
grounded, logically it should make no difference WHERE the shield is
grounded to, but from an RF standpoint, the shield connection to the
vertical must be horizontal with the connection to the driven element.
On Multi-Band J-Poles with single coax feed, we place a horizontal
shorting strap between the connect points of the unfed stub and
vertical element to get the antenna to work properly.
It's been too many years ago that I studied this stuff to remember
why.

>What if you used a non insulated pvc type pipe to connect the stub and
>verticle element?
Wrong Analogy! Although we use the word Stub, a J-Pole consists of a
1/2 wave vertical element, affixed to one leg of a 1/4 wave U-shaped
matching transformer.
By making the horizontal member from PVC and not contiguous with the
two legs of the U, you would not have a U shaped matching transformer.
FWIW: The U does not have to be vertical, it can be horizontal as is
the upper matching transformer on a Stacked-J and BOTH stubs become
affixed to the vertical elements.

I have seen a unique antenna design that looks like a J-Pole, but the
1/2 wave vertical is insulated from the U-Shaped matching section,
just as a ground plane is insulated from its 1/2 wave vertical.
The feed for this type of antenna was quite hairy to get just right!
If I recall, a brass rod extended up into the vertical about 8 inches
to it's connection point and the lower connection point was similar to
a J-Pole.

|
|Didn't you ever use an 8 to 1 *MULTIPLEXER* chip to change
|parallel BAUDOT to serial BAUDOT?

Actually, no. I have however, worked on monopulse RADAR missile
seekers where the requirement for three phase and gain matched
receiver channels (sum, delta elevation, delta azimuth) was reduced to
two by time-sharing one delta channel. You can call this multiplexing
if you want (TDMA?), but as an r-f guy, I have a different take. At
any point in time the only data in the delta channel was *either*
elevation *or* azimuth, not both elevation *and* azimuth. (* maybe a
digital system after all? :-)

|The parallel BAUDOT bits
|are time-multiplexed into a serial bit stream by the
|three clock bits. The first parallel bit is hard-wired to
|yield a start pulse and the last two parallel bits are hard-
|wired to yield a stop pulse. The center five parallel BAUDOT
|bits are time-multiplexed from parallel to serial by five
|states of the clock.

Fine, but how does this support your statement above to which I
responded?

I think I'm catching on tho...in ham terms, a digital multiplexer is
like a two-meter repeater; only one guy can talk at a time. I'm more
familiar with analog multiplexers, a 20-meter DX pile-up for instance,
where everybody talks at once. [g].

Hiya,

I have an MFJ 9040 and want to make it totally portable. No tuner, etc. I am thinking about a longwire cut to frequency but how do I connect it? Won't I need to use some feedline? If so, how do I connect it to 20-22gg wire? I need to make this as cheaply as possible. Interested in just throwing the antenna up or down a balcony etc.

> Is the OCF multi-band antenna a dog on 20 meters?

I ran into the same problem at the N2EY/W3RV Field Day site. The NW/SE 80M G5RV cooked on 80 & 40 but it wasn't so hot on 20/15 I assumed because of the "lobes to nowhere useful" problem discussed above. So I built conventional coax-fed 20 & 15M dipoles strung end-to-end and installed them parallel with but lower than the G5RV from another pair of trees. From here near the NE coast we now have major lobes aimed southwestward on all four bands which seem to cover the whole country and Canada quite well except directly off their ends. I suspect part of the success of the 20/15M dipoles vs. the G5RV is attributable to lower tuner losses, we don't need a tuner for 20 & 15.

<stryped@hotmail.com> wrote
> So, if coax is kept inside the tubing, there is no stray rf and
> therefore a choke or balun is not needed?

Gary did a good job of answering your questions, but I am reinforcing what he said.

By design, the J-Pole may allow feedline radiation: None, a little, or a lot, depending on the users unique configurations of feedline length, design frequency, and accuracy of matching-stub construction, etc. Therefore an isolating 1:1 Balun or coils of feedline (choke) at the feedpoint of the antenna are highly recommended. Routing the coax inside the variable lenth of the main antenna length to get to the shorting (matching) stub would have little or no effect on preventing feedline radiation, if your design was subject to it in the first place.

>
> Are you saying the shield must be grounded to a surge supressor to
> prevent lightening stikes?

Not everyone is subject to lightning, and for some it is rare enough that they choose not to worry about it. But if lightning protection design is used, it requires shield-grounding. Coax shield (braid, solid, any kind) must be grounded, and at several points depending on the tower height, mast, length of feedline, etc. In order for lightning arrestors (more commonly called SPD or Surge Protection Device) to work properly, the coax shield must be well grounded *before* it is connected to the arrestor/surge device. That's another whole subject and we have explained your J-pole doesn't "need" grounding several times. A copper J-Pole however, is about as attractive a point for lightning attachment as you could offer. It is also subject to the same levels of static electricity that any airborne antenna picks up. Act according to your individual desire for survival there.

>
> My ideas was to run the wire inside and even make the coaxle
> connections inside the tubing with wire terminals and screws, so as to
> keep everything neat and weath proof.

That would be a really neat and pretty wx-proof design, but a lot of work. There might be an easier way to wx-proof it, mentioned later.

>
> What if you used a non insulated pvc type pipe to connect the stub and
> verticle element?

The cross-connector is a shorting, matching "bar", as Gary warned you against using the word "stub" if that was going to confuse anyone because it

is not a waveguide or filter or anything else the word stub is normally used to describe. Therefore it could never be made of an insulating dialectric such as PVC. You could however hot-dip coat the whole antenna in plastic or rubber if you wanted to really wx-proof it, and this would eliminate the difficult inside-assembly of coax in the tubing that your proposed.

One final note: the J-Pole is no miracle antenna. It's has zero gain when compared to any vertical antenna, and its entire attraction is it "fairly" easy construction, and very inexpensive construction materials. To get as *reliable* a vertical antenna for marine use that I required, might have cost well over $100. At or above that level the vertical antennas of 5/8 wavelength can normally provide gain of 6-10 dbi, and I do not want to get into what that is compared to as it has been hashed over a million times. I would leave it at "there will be considerable gain possible in vertical designs over the J-Pole". You have to be willing to pay for that. Most users are happy with J-Pole performance so it's record stands pretty well on its own.

> wb6wsn

Hi Ed, using high powered lasers to "paint" a thunderstorm cloud has been done, and whether reliably or not, was able to trigger lightning. It hasn't translated into practical protection schemes yet, but that could simply be economics. As a means of triggering lightning to a safe point away from vulnerable assets, it still leaves the possibility that some storms are so powerful that nothing short of an extensive, multi-point array of lasers could ever offer protection at an individual point. It is generally so much less expensive to employ catenary wires overhead, build faraday-cages around, and position air terminals in appropriate areas than the costs of such a laser system. There would also be a new class of airspace required for operation of such lasers. Something like a "no-fly zone" in fact! ;-)

Hi Ed,

There certainly seems to be a mixed bag of what's useful out of the
old USSR. However, their math software applications have been killers
in the capitalistic marketplace. One other jewel came from their
rocket division that built the most powerful engines known, and then
the bureaucracy ordered them scrapped because they abandoned their man
on the moon program.

The engineer in charge deliberately ignored this order and had
something like a couple of hundred wrapped up and put into storage.
They are making quite a killing on selling those right now.

Another story is their development of a supersonic torpedo. That's
right, a jet powered torpedo that can dart through the ocean at
600MPH. It was speculated that it was the cause of the sinking of
their submarine, the Kursk. It was thought that the propellant lit
off in its bay, and the rest is history.

==========

You forgot to say what an MFJ 9040 is. I've never heard of it. Does
everybody except me always have one?

But you have no problems.

Just throw some wire over the balcony or out of the bedroom window, cut to a
length of about 1/4 or 3/4-wavelengths at the frequency you intend to use it
at, and plug the near end of it into the coaxial output socket of the
transmitter.

At least as important is the ground connection. For that use large aligator
clips at the ends of shortish lengths of 18-gauge, plastic-insulated,
flexible, multi-strand wire and connect to the domestic plumbing system.
Hot or cold water or central heating pipes, or preferably several of them,
will do fine.

To save yourself the inconvenience of withdrawing the antenna to prune it,
make the antenna wire length a little longer than 1/4 or 3/4-wavelengths and
connect it in series with a 300 pF variable capacitor.

Don't worry about the SWR if the transmitter doesn't mind.

Hi Greg,

Both your description above AND the manual scream "use a tuner."

A "tuned" antenna is only tuned to its environment, and unless you
take that environment with you on the road, that antenna is NOT going
to be tuned. However, there is much to be said for sloppy
installations being so lossy as to match every time. A low dipole
often so qualifies. However, a longwire cut to frequency (something
of a contradiction in terms, by the way) would then depend on the
ground path attached to your MFJ. If you are thinking of cut to
frequency in the sense of a halfwave, then you are driving a severe
mismatch (which that manual also screams may lead to spurs).

Get the drift?

Some tuners don't have a bypass function. Perhaps his doesn't.

You're right. I was thinking about the gain of a 2x5/8WL
dipole over a 1/2WL dipole.

> Ian.

The feedpoint impedance of a dipole varies with frequency from a
low value of about 50 ohms to a high value of about 8000 ohms.
In between, it can look like 1000(+/-)j1000 ohms.
Baluns with a high transforming ratio try to take the impedance
lower so, for instance, with a 4:1 balun, the above values would
ideally go from 50 ohms to 12.5 ohms, 8000 ohms to 2000 ohms,
and from 1000+j1000 ohms to 250+j250 ohms. You can see that the
second set of values have a smaller absolute range than the first
set, thus making them an easier match for the tuner.

That's the simplified version. There are disadvantages to using
baluns with a high transforming ratio.

DON'T FORGET!!! When the paired mates, ARGON and NEON, are "coupled,"
they produce

LIGHTNING

aka [BLITZ!!!] ... they both form absolutely NO OXIDES

http://carpathian_bronze.tripod.com/antarii_deck2.html

interesting related topics:

SUPER COOLED LIQUID WATER

-- Water vapour deposited on low-temperature (<140K) is known to form
an amorphous phase, termed AMORPHOUS SOLID WATER (ASW), that is
metastable with respect to crystalline ice. There is still a debate
about whether this amorphous form of water transforms to a metastable
liquid above the GLASS TRANSITION temperature at 136K and before
crystallization near 160K. Furthermore, if the amorphous solid does
melt into a liquid, a question remains as to whether this liquid is a
metastable extension of supercooled liquid water OR A DISTINCT
THERMODYNAMIC PHASE.

DEUTERONOMIC REFORM -- 622 BC. King Josian of Judah made a Book of Law
which vigorously enforced a reform in which all rural religious
sanctuaries and fertility-focused BELIEF NETWORKS were purged and
annihilated and ALL WORSHIP was commanded to be performed at the TEMPLE
OF JERUSALEM.

The word "Hebrew" [in Hebrew!] is " 'Ibri ", which means "one from the
other element".

The Pentateuch arose AT THIS TIME and was known as Deuteronomy, or
spoken by "D," otherwise known as DEUTERIUM. This is when the
Israelites were first to have been "chosen". This was also the first
instance of monotheism in Judaic lore.

Today, "D" is called 2H and is known as HEAVY HYDROGEN. It is rarely if
ever a natural atomic species. The nuclear fusion of both deuterium and
tritium releases an enormous amount of energy and is the essence of
thermonuclear weapons.

HEAVY WATER
-- D2O is also called DEUTERIUM oxide, a "water" composed of deuterium
(HEAVY HYDROGEN), a hydrogen isotope with a mass which is DOUBLED that
of regular hydrogen), and Oxygen.
H20=Water

SiO2=Silicon Dioxide
CO2=Carbon Dioxide
2H=Heavy Hydrogen (is it real???)

Heavy Water has a molecular weight of about 20. Water has a molecular weight of about 18.

Unmitigated and persistent "electrolysis" of 100,000 gallons of water, until only a few drops remain, yields nearly "pure" HEAVY WATER (deuterium oxide). These few drops of heavy water can now be used as a moderator of neutrons in NUCLEAR POWER plants.

GAMMA RAYS -- gamma rays are penetrating electron-magnetic RADIATION of the same nature as an X-RAY though usually of somewhat shorter wavelength, emitted spontaneously by some RADIOACTIVE substances. Even a chance encounter of a gamma ray with a SINGLE genetic NUCLEOTIDE results in a toxic biochemical effect and results in DNA/gene mutation. Gamma Rays originate in PARTICLE--ANTIPARTICLE ANNIHILATION. The absorption of gamma rays by nuclei causes PHOTODISINTEGRATION and PHOTOFISSION of a nucleus or NUCLEI. To make a simple analogy, think QUASARS and their ever present BLACKHOLE companion, with its insatiable ACCRETION DISK, sucking up all light in its reach at speeds of 6.5 million MPH, and reducing billions of suns and stars into a teeny cosmic compression.

Look on Google for "fused disc" AND "cable".

Most Cable TV companies stopped using it when they started using frequencies
above 300 MHz.

This cable acts as a filter around 350 MHz.

The 8-bit ASCII could be generated using a digital multiplexer.
If one had a 10-bit digital multiplexer chip, one could use an
ASCII byte stream into it to generate serial ASCII. That's eight
separate input bit data streams being time-multiplexed into one
output data stream and that comes under the definition of multiplexing.

One problem here is the age of my vocabulary. When I learned and
worked on this stuff, there were digital multiplexers and decoders,
i.e. the word "encoder" was not in common use yet. Reference:
"Fundamentals of Logic Design", 2nd edition, Charles H. Roth, Jr.,
copyright 1979, pages 184-190. "Multiplexers" and "decoders" are
described in detail but absolutely no mention of "encoders" anywhere
in the book. Back then, "encoders" were included in the definition
of "multiplexers".

Perhaps. But I can be as kind and courteous as the next guy when it
is reciprocal. Over one hundred hams got their Novice tickets via
classes that I taught at the local community college and I *never* had
a complaint about disrespecting any of them because of their
ignorance. Some of them even repeated the course just for the fun of
it...and I might add they were paying tuition. Likewise the tech
course I taught at the local Air Force base and the grad students I
tutored in a microwave measurements course my boss taught at the U of
Az.

That said, if one of them had told me "You're entitled to your opinion
on this seemingly controversial topic", I would have shown him the
door. I actually like helping the inexperienced, but I don't suffer
fools gladly.

Hello,

I apologize if this is a question has been asked a million times - but a google search has beeen overwhelming.

I bought a Teac SL-D88 radio for our kitchen, but the FM reception is terrible. We live in a stone house (18 inch thick stone walls).

We have an old (currently unused) TV antenna on our roof that has a coaxial cable running into our basement. The kitchen radio has an external antenna that consists of a single wire (no dipole or coaxial hook-up).

Can I connect the radio to the antenna, and how would I do that?
Thanks in advance.

Michael

419. Resonant and Non-resonant Radials

Newsgroup: rec.radio.amateur.antenna
Date: 2005-01-08 21:51:49 UTC
From: Reg Edwards <g4fgq.regp@ZZZbtinternet.com>
Message-ID: <crpklksng1@titan.btinternet.com>
Source record: 84057

The only radials on which resonance is truly effective, whether they be coil-loaded or not, are the elevated variety. ie., those which are roughly 1/10 wavelengths or more above ground level. At lower levels the loss induced in the ground or in the loading coils, although perhaps not immediately apparent, can be undesirably high.

Radial proximity to the ground has two effects - first is the obvious loss induced in the ground due to soil resistivity. Second is the more insidious reduction in propagation velocity along the radials due to soil permittivity which makes a mess of the resonant frequency.

For low-height radials it is incorrect to use calculated lengths from the usual formulae. Depending on soil constants (and radial angles) it is necessary to shorten radials by careful pruning aided by readily available antenna impedance analysers.

When radials are lying on the ground, with ordinary soils, the propagation velocity is roughy half of the free-space velocity. Consequently, the physical resonant length is only half of the value when radials are well elevated.

But because of the higher loss in radials lying on the ground the pruning to obtain resonance is much less critical. The resonant Q may be down to 2 or 3.

When radials are buried to a depth of fractions of an inch or more the velocity factor can fall very fast to as low as 0.1 at the lower HF frequencies. It depends on moisture content of the soil. Pure water has a very high dielectric constant (permittivity) of 80.

Incidentally, soil relative magnetic permeabilty, which also affects velocity factor to the same extent, always remains in the neighbourhood of unity simply because the pure iron and similar magnetic materials content of ordinary soil is quite small by volume.

So at HF a buried radial wire (unless in dry Sahara sand) is a high-loss transmission line with a low velocity factor. Resonance effects are practically non-existent. For usual length radials line input impedance is Zo of the line. The lossy effects are due only to the resistive conponent of Zo. The reactive component is of no consequence because it is tuned out simultaneously with a vertical antenna reactance.

The resistive component of input impedance of a set of buried radials is a complicated function of frequency which does not bear a very close relationship with soil conductivity. So the actual value of soil conductivity at VLF, even if it is known, and it seldom is, entered in modelling programs is of little use.

Only at HF, say at 30 MHz and above, in very high resistance soils, do small resonant effects re-appear. And not surprisingly ground losses decrease down to values experienced in soils of very low resistivities.

When the soil is an insulator ground losses are zero. Does maximum ground loss occur when ground resistivity is 377 ohm-metres at which no reflections occur.

For an approximate analysis of the performance of a set of buried radials, download program RADIALS2 from website below. Download in a few seconds and run immediately. You may be pleasantly relieved at the short lengths and nunber of radials required to acheive a reasonable performance. It won't be the oft-advertised, magazine magic number of 120 which is divisible by 60, 30, 20, 15, 12, 10, 8, 6, 5, 4, 3 and 2.

I'm sure you've read these letters asking you to send $1 to six different addresses. Putting your home address or mailing address on the internet can be risky, but through PayPal all you have to provide is your email address. It's safe and easy. Just go to www.paypal.com and set up your FREE account! No credit card is needed. I am not a gullible person and have never trusted things like this, but I gave it a try. Hey it's only $6. I figured at least 6 people would respond out of the millions of people that use the internet. You should give it a try too! You have nothing to lose, and thousands to gain! Read on for the letter that I found (of course, I added my PayPal e-mail on #6)...

HOW TO TURN $6 INTO $6,000+!!! THIS REALLY CAN MAKE YOU EASY MONEY!!! IT WORKS!!! BUT YOU HAVE TO FOLLOW IT TO THE LETTER FOR IT TO WORK!!!! A little while back, I was browsing through newsgroups, just like you are now and came across an article similar to this that said you could make thousands of dollars within weeks with only an initial investment of $6.00! So I thought, "Yeah, right, this must be some kind of scam" but like most of us, I was curious, so I kept reading. Anyway, it said that you send $1.00 though PayPal to each of the emails stated in the article. You then place your own email address in the bottom of the list at #6, and post the article in at least 200 news groups. (There are thousands) No catch. That was it. So after thinking it over, and talking to few people first, I thought about trying it. I figured what have I got to lose except $6.00, right? Like most of us I was a little skeptical and a little worried about the legal aspects of it. It follows the same regulations as the "mailed chain letters, which according to the U.S. Post Office (1-800-725-2161) is indeed legal! Then I invested the measly $6.00. Well GUESS WHAT!!? Within 7 days, I started getting money in my PayPal account! I was shocked! I figured it would end soon, but the money just kept coming in. In my first week, I made about $20.00. By the end second week I had made a total over $1,200.00!!! In the third week I had over $10,000.00 and it's still growing. This is now my fourth week and I have made a total of just over $36,000.00 and it's still coming in rapidly. It's Certainly worth $6.00. I have spent more than that on the lottery!! Let me tell you how this works and most importantly, why it works? Also, make sure you print a copy of this article now, so that you can get the information off of it as you need it.

$$

REQUIREMENTS: You must have a confirmed PayPal account. If you do not have a PayPal account you can go to www.paypal.com and follow the instructions to set up a free account. In order to place the initial $6 into your account, you will have to confirm your bank account with

PayPal (which may take a few days). PayPal is 100% secure and is used my millions of people world wide. Confirming a www.paypal.com account simply means (1) PayPal will first ask you to confirm the email you used to sign up your PayPal account by sending you an email with a link for you to click to that email. As soon as you click that link your email is confirmed. (2) PayPal will then make two small deposits into your bank account if you set up your PayPal account with a checking or savings bank account. Or PayPal will make two small deposits to your credit card if you set up your PayPal account with your credit card. Then after a few days (it takes up to a few days for these deposits to appear in your bank account or on your credit card statement) then after a few days you go back to the www.paypal.com website and sign in. Then you click where it says this account is not yet confirmed. A screen will pop up that gives you 2 boxes to fill in. You then enter the numbers of the 2 small deposit amounts (two separate 2 digit numbers) that were deposited to your bank account or credit card. Now you have a working and confirmed PayPal account and can receive payments.

$$

[STEP 1]
Send, though PayPal, $1.00 to each email on the below list. Make the subject of the payment "Email List" and in the comments, write "PLEASE PUT ME ON YOUR EMAIL LIST." What you are doing is creating a service by this - and best of all you are not giving your address to anyone you do not know. THIS IS ABSOLUTELY LEGAL!! YOU ARE CREATING A SERVICE. Here are the latest PayPal e-mails on the e-mail lists:

#1)brittany...@excite.com

#2) mth...@renc.igs.net

#3) Mishav...@aol.com

#4) nike31...@aol.com

#5) careent...@hotmail.com

#6) jjrvn...@hotmail.com

www.paypal.com

Subject of Payment: ***Email List***

Comments: ***PLEASE PUT ME ON YOUR EMAIL LIST***

[STEP 2]
Now take the #1) email off the list that you see above, move the other addresses up one (6 becomes 5 & 5 becomes 4, etc) the put YOUR email address (the one used in your PayPal account) as #6) on the list. **MAKE SURE THE EMAIL YOU SUPPLY IS EXACTLY AS IT APPEARS IN YOUR PAYPAL ACCOUNT**

[STEP 3]
Change anything you need to, but try to keep this article as close to original as possible. Now, post your amended article to at least 200 newsgroups, message boards, etc. (I think there are close to 32,000 groups) All you need is 200, but remember, the more you post, the more money you make - as well as everyone else on the list! In this situation your job is to let as many people see this letter as possible. So they will make you and me reach!!!! You can even start posting the moment your email is confirmed. Payments will still appear in your PayPal account even while your bank account is being confirmed.

$$$

DIRECTIONS ON HOW TO POST TO NEWSGROUPS/MESSAGE BOARDS.

[Step 1]
You do not need to re-type this entire letter to do your own posting. Simply put your CURSOR at the beginning of this letter and drag your CURSOR to the bottom of this document, and select 'copy' from the edit menu. This will copy the entire letter into your computer's temporary memory.

[Step 2]
Open a blank Notepad file and place your cursor at the top of the blank page. From the 'Edit' menu select 'Paste'. This will paste a copy of the letter into notepad so that you can add your email to the list.

[Step 3]
Save your new Notepad file as a .txt file. If you want to do your postings in different sittings, you'll always have this file to go back to.

[Step 4]
Use Netscape or Internet Explorer and try searching for various newsgroups, on-line forums, message boards, bulletin boards, chat sites, discussions, discussion groups, online communities, etc. EXAMPLE: go to any search engine like yahoo.com, google.com, altavista.com, excite.com, then search with subjects like "millionaire message board" or "money making message board" or "opportunity message board" or "money making discussions" or "business bulletin board" or "money making forum" etc. You will find thousands and thousands of message boards. Click them one by one then you will find the option to post a new message.

[Step 5]
Visit these message boards and post this article as a new message by highlighting the text of this letter and selecting 'Paste' from the 'Edit' menu. Fill in the Subject, this will be the header that everyone sees as they scroll thru the list of postings in a particular group, click the post message button. You're done with your first one! Congratulations! THAT'S IT!! All you have to do is jump to different newsgroups and post away. After you get the hang of it, it will take about 30 seconds for each newsgroup! **REMEMBER, THE MORE NEWSGROUPS

AND/OR MESSAGE BOARDS YOU POST IN, THE MORE MONEY YOU WILL MAKE!! BUT YOU HAVE TO POST A MINIMUM OF 200** That's it! You will begin receiving money within days! **JUST MAKE SURE THE EMAIL YOU SUPPLY IS EXACTLY AS IT APPEARS ON PAYPAL.**

Have fun!

How would you go about tuning a ground plane antenna? Is a ground plane
a good antenna for 2 meters/440?

On another note, I have read about discone's being very broad banded.
Are these the best antenna for scanner listening?

This is really funny! On the 5th, someone posted a question about how a dish tracks a satellite, and I told them to go
look up monopulse techniques for the answer and got roundly slapped around the head and shoulders for offering a non
answer. Now, here the three channel monopulse technique appears in a discussion of AUTOMOBILE TAIL LIGHTS for gosh
sakes.

Go figure.

A ï¿½-wave groundplane, a ï¿½-wave dipole, a J-Pole or 5/8-wave ground
plane in most typical installations according to NEC analysis will not
vary more than a dB at best.

Remember a receiving station can hardly detect a dB difference.

More like a "dead-fly" zone. Yeah, aircraft (and satellite / astronaut) protection are not trivial concerns when you start squirting power into the air.

BTW, I seem to recall the use of small (sounding?) rockets used around the perimeter of the Kennedy launch complex. I don't recall if these rockets trailed a thin wire, or if their exhaust plume was sufficient to trigger a lightning discharge. Anyway, I thought I recall these small expendable rockets being used as a lightning diversion technique to protect the exposed launch vehicle. (Yes, I know they also use catenary wires from the tower to the ground, but the rocket technique was supposedly to condition the area around the vehicle just as launch occurred, and the tower was moved away from the vehicle.)

We Americans used to chuckle about how, in Germany, everything was
prohibited except that which was specifically allowed. And now, we have
Covenants, planning commissions, the EPA, the FAA, the FCC, OSHA, and
agencies yet unformed, should we try to stick a wire up in the air. We've
learned a lot from Europe, and don't remember Pogo at all.

Yes/Yes, and there are a number of verticals with referenced gain far in excess of the more or less unity-gain J-Pole. The specific ones I mentioned are Marine. Like a vertical-dipole the J-Pole is a "complete" antenna and requires no radials, I doubt that it could even benefit from them. And the gain is referring to transmit, not receive, as all verticals are pretty equal in reception (and it's not always pretty ;-)

What is your target for 2 meters? General area coverage or specific directional? Need to null out signals or interference from specific directions? Look at aYagi. J-Poles are not for anything special, just good general coverage at about $10 in parts. At that job they have become very popular antennas!

Yessir Ed. At NASA Wallops Island (Eastern Shore, VA) they regularly launch sounding rockets. We have had one land well off course about 300 yards off the Virginia Beach Oceanfront late one night. I was able to help call off the extensive search involving air, sea and land assets when I convinced District to check with Group Eastern Shore (who I had heard make the Securite' announcement earlier, warning of the rocket launches). Witnesses at the beach had reported a flaming plane crash in the water. When the CG Helo pilot realized that it was probably a rocket, (and there were still more scheduled) he bugged out fast.

As to triggering lightning with rockets, yes they do trail wire, and this method of lightning experimentation provides excellent results. Makes sense they would clear the air first before a launch, but I think they are pretty sure lightning isn't likely before they light one of those candles, huh? The static charges from a rocket alone must be impressive. Maybe it could attract lightning from a lot farther than normally considered in the risk-zone.

Hi OM,

As far as performance? Absolutely no difference to it even if it were
elevated 1000ï¿½F above that to compare.

- Well maybe someone with enough sophisticated equipment might notice
a dB difference - then they would whack the side of the gear to clear
that up - nope, no difference....

You need to come to terms with just how imperceptible 1 dB is (zilch,
in technical terms), and how much power it takes (about 12%, just more
$ to burn) to make that imperceptible difference. The dollar has lost
30% of its value in the world market in the last few years - have you
noticed? This may not be one way to appreciate 1dB, but it does
reveal how relative changes go unfelt.

A 1/4 wave ground plane is tuned by varying the length of the
radiating element. Calculate the length, add a bit for good measure,
build it then tune it by pruning the length (in small increments).
The tuning can be done using an SWR analyzer or as most of us do, with
a radio and an SWR meter.

Discone's do offer broadband coverage, though I don't have direct
experience to say they actually work well, great or poorly. I do know
that for my scanner I use a 1/4 wave ground plane that was built for
220 MHz and it works fine - for a reference point though I am in an
urban area and most of what I listen to is within a 15 mile radius.
In order to decide what's best you should first establish your
purpose; are you in a fringe area, do you need directional coverage,
do you scan a wide range of frequencies or are your listening
interests all in the same "neck of the RF spectrum"?

I used to use a lot of the 3/4 " foam filled CATV line and still have
probably 200 to 300 feet left. At HF it works well and does not
require matching sections unless the operator is a perfectionist.

It's much more rugged than the fused disk stuff and water isn't
normally a problem.

438. Ground radials -- the practicalities?

Newsgroup: rec.radio.amateur.antenna
Date: 2005-01-09 11:33:44 UTC
From: news <news@care4free.net>
Message-ID: <JUq0fdFoZR4BFwPh@care4free.net>
Source record: 83976
Cross-posted to: rec.radio.amateur.antenna,uk.radio.amateur

I need to improve my ground system, and am thinking of burying some radials under the lawn.

[I realise this is not the most efficient way to do it from an electrical point of view, but the alternative approach of installing the radials above the ground is completely out of the question, for aesthetic reasons].

Some practical questions:

~~~~~~~~~~~~~~~~~~~~~~~~~

1. What is the "best" type of wire (or braid) to use for the radials?

2. How do I bond the radials together? (I guess my 15-watt soldering iron won't be up to the job ...).

3. What kind of solder and flux should I use?

4. What precautions should I take to minimise the effects of corrosion at the joints?

5. How deep should I bury the radials? Two inches, six inches, 12 inches?

6. Is there anything else I should know?

~~~~~~~~~~~~~~~~~~~~~~~~~

We are on heavy clay soil that alternates between being very dry and very wet.

My main interest is in the lower hf bands (40/80/160) and possibly 136kHz.

Well, Ed,
It is difficult to produce oxides without oxygen, but bullshit is easy to
come up with.

Whatever you can get cheaply, as you need a lot.

Insulated is fine- the soil (rf) conductivity is poor (or you'd not need radials) so the benefit from have bare wire is minimal. Insulated will stop it corroding.

> 2. How do I bond the radials together? (I guess my 15-watt soldering

Bring them to a 'star point' which is your earth point and it should have a normal earth stake. Make sure this is bonded to you PME point for safety by 10mm^2 wire.

If you solder, use ordinary multicore solder.

>
> 4. What precautions should I take to minimise the effects of corrosion

Self amalgamating tape or use conduit boxes and 'pot' with epoxy.

>
> 5. How deep should I bury the radials? Two inches, six inches, 12
> inches?

Depends- this is as much to do with what the land is used for. In the past I've used a spade to make a shallow 'slit', maybe 2" deep, in the lawn and

pushed wires into that.

In a flower bed or vegetable patch that wouldn't be deep enough.

Don't forget patios. Our patios have radials under them. Also, you can run wires around the bottom of fences etc, by paths.

> 6. Is there anything else I should know?

Don't forget that safety bonding!

I would use a blowtorch (But I am used to using one).
The secret is not to overheat things.
Its a kind of dabbing technique to get up to temperature.

Hi,

We know that during the emission of a radiotelescope (rare, for tests or to send SETI msg, Hi!), the radiation can sterilize people working in the dish. Has someone some idea of the power require to produce such a effect or any generic graph (from IEEE standards ?) showing the risk vs frequency or emitting power ? I have one, http://www.astrosurf.com/lombry/Radio/table-power-field.gif but I would like to get a better idea of the power require (in W, Jy, etc).
If I had an idea of the require dBi and W , I could compute the EIRP and all concerned values.

Thanks in advance

Thierry, ON4SKY

Health Canada's Safety Code 6.

Hint - it's not a dish issue with huge dishes. It might be a feed issue in the worst case. The bigger the dish, the less the issue (the feed being further away).

Likely, the 600mW cell phone is worse. And the 5w hand held W/T is even worse than that.

If you own a strong magnet and an electric stove, hold the magnet in your hand and turn on one stove top electric burner element to max. Bring the magnet close to the element and feel the very strong vibrations. (Don't burn your hand.)

>What type of verticle are you talking about, like a ground plane? Would
>a ground plane be a better antenna for 2meters?

Check out my Stacked-J for 2 meters. It is a J-Pole on top of a
J-Pole.
I don't know the difference in gain, but in comparison to a regular
J-Pole on the same mast, the Stacked-J outperformed it hands down.

From St. Louis County, MO I could reach both UMR (Rolla) and UofC
(Columbia) repeaters on the Stacked-J at 30 watts, a little noisy on
their end, but I was clear. On a single J-Pole I could not bring up
their repeaters even at 50 watts.

The Stacked-J can be found at http://archimedes.galilei.com/raiar
It's under Antenna's.

Hi Ian

I had over 3,500 feet of radials under my HF9VX/w160.

They were buried only about 1 inch deep overall.
I used a meat cleaver and rubber mallet, placing an open eyehook through the hanging hole on the meat cleaver.
I stretched the wire out first, then let it pass through the eyehook.
As I cut along the edge of the wire to make the hole in the ground, the eyehook would pull it down below the surface.
The job went fairly quickly!

I used some 12 and some 14 guage insulated solid copper wire, whatever was on sale the cheapest, hi hi.....

At the antenna base, I drove an 8 foot ground rod, allowing it to stay above ground about 4 inches.
Each radial came up to this ground rod and made a 90 degree turn upwards.
I used a cheap pencil flame propane blowtorch and Copper Phosphorus Bronze brazing rods (low melting point, good adhesion to copper), affixing each wire to the ground rod.
I then welded an insulated braided 8 guage wire to this for later connection to the antenna.
After all the radials were in place and welded to the rod, I slipped a 3/4 inch copper pipe over the ground rod and down to the radials and filled it with silicone caulk.
Then, using a hose I washed out the dirt under the radials around the ground rod so that I could (after it was dry) get about a 1 inch deep layer of silicone around the ground rod and ends of all the radials so that the insulation was covered back about 1 inch and about 1/2 inch above the copper pipe.

Because the HF9VX has a COIL near ground level, I cut the bottom out of a vinyl Cylindrical flower pot and slipped this over the antenna mount and ground rod. It was stuck into the ground about an inch or two, down to the tops of the radials. To keep grass/weeds from growing, I also dumped a 4lb box of rock salt into the container.
I used a PVC sleeve over the antenna mount, so the salt would not get to the aluminum.

Another way is to go to your local electrical wholesaler
(assuming he will deal with you now we're past Jan 1st/Part P)
and buy one of those chocolate-box-like strips for commoning
up 6mm green-and-yellow to clamp all the wires together.

Some of my literature recommends against braided or woven conductors
as having too high a surface resistance to lightning and RF,
especially if they get corroded. Wide smooth surfaces are better.

You might try Lowe's Home Improvement or Home Depot -- they both sell
500-ft. rolls of #12 copper wire for about $20. That'd save you going
to the poorhouse, on this :-)
>
>2. How do I bond the radials together? (I guess my 15-watt soldering

A Weller SP-120 (120 watts, 1/2" tip) or SP-170 (170 watts, 5/8" tip)
would do the job. Either of these is also great for soldering coax
plugs (I have the SP-170 & it's a barnburner). If you can't find the
irons locally at a hardware or hobby shop, a Google search brings them
up, online.

But how good is the efficiency when the balun/transformer is working
between completely the wrong impedances (which will be most of the
time)? My understanding (and limited experience) is that most of your
power simply heats up the ferrite.
Ian.

Some of us have encountered the wrath of our local planning committees when erecting antennae that seemed reasonable to us, but perhaps unreasonable to SFB neighbours.

Could we conceive of an antenna, even possible an HF beam, that folds away into a single rod-like structure when not in use?

I have in mind the way in which quite elaborate antennae and solar cells unfold from a satellite once it reaches orbit.

Such an antenna, if it were to be deployed only during the hours of darkness, might also serve the needs of those who are obliged to use stealth antennae due to restrictive covenants on the buildings used as their shacks!

Good idea. Bury anything that will conduct, eg biscuit tins! I spent ages unwinding and burying the coils from old TV CRTs. 40 years ago (I was a 160m nut) I bought a very large reel of bare 18 swg "garden wire" from local hardware store. It looked like copper but too light and seemed to be an ali alloy. It was buried in around 2"-4" slits in 100 - 150' lengths in clay-ish non-acid soil. Still looks in good shape. I used choc block connectors to join the wires in pairs or triplets, soldered the group and left a tail to make the next larger group. Used heavy auto earthing braid for final lead into ground floor shack.

Was it worth the trouble? Yes. With a ~200' inverted L (3/8th wave on topband), no problem working Ws on a 500mW transistor (germanium!) box. Dead band with earth disconnected.

Why not?

>Some practical questions:
>
>~~~~~~~~~~~~~~~~~~~~~~~~
>1. What is the "best" type of wire (or braid) to use for the radials?

Something that is cheap (so you can have lots of it) and non-corroding
(so you don't have to re-lay it every year).

>2. How do I bond the radials together? (I guess my 15-watt soldering
>iron won't be up to the job ...).

Use a car battery clamp and plenty of grease.

>3. What kind of solder and flux should I use?

None at all. See above.

>4. What precautions should I take to minimise the effects of corrosion
>at the joints?

See above.

>5. How deep should I bury the radials? Two inches, six inches, 12
>inches?

Whatever you find most convenient.

>6. Is there anything else I should know?

You will never lay enough radials to turn your garden into a
highly-conductive metallic mirror, the next best thing you can do is
to provide the lowest ohmic contact for your vertical. If your
vertical has a radiation resistance of R ohms and the ohmic contact
with the ground is Z ohms, the efficiency of your system is given by
R/(R+Z). Consider a short vertical with a ground rod might have R = 10
and Z = 150, you can see the efficiency is pretty low at ~6 percent.
So 94 percent of your RF is heating up the earthworms &c.

>We are on heavy clay soil that alternates between being very dry and
>very wet.

I suggest you start with a couple of tons of well-rotted farmyard
manure. You need to work on that clay and turn it into something
better both horticulturally and electrically.

>My main interest is in the lower hf bands (40/80/160) and possibly
>136kHz.

In that case at 136 kHz R above might be .0001 ohms or worse, and your
efficiency will be very low. Get as much metal in the ground as
possible. Avoid loops.

Whatever you can get a lot of at a cheap price, and isn't going to
corrode immediately it's buried. That means NOT braid or bare stranded
either.

Bare or insulated solid wire is fine, and likewise insulated stranded
wire.

>2. How do I bond the radials together? (I guess my 15-watt soldering
>iron won't be up to the job ...).
>
I used a horizontal busbar of copper tube, supported by a token ground
rod. Each radial was looped round the busbar and secured with a twist,
and finally the whole lot was soldered with a blowtorch (used at a
careful distance).

>3. What kind of solder and flux should I use?
>
Ordinary tin/lead. I used Fluxite paste and rinsed it off afterwards.

>4. What precautions should I take to minimise the effects of corrosion
>at the joints?

Do 1/4 wave ground planes work well for 2 meters? (Send and receive).
Would they work as well as a j pole? What if you use different size
elements?

I just did not know what a discone would do for 2 meter send and
recieve compared to a ground plane.

On the scanner, I live in a fringe area for police but can pick up the
police on a homemade wire 1/4 wave for 450 mhz about 20 miles away.

What eventually I would like to do is pick up air traffic. And also
pick up various other frequencies like ambulance, state police, etc.
or your scanner do you use one antenna or several?

As suggested, lots of wire. Doesn't matter to the RF if it's insulated or not (it will matter as far as corrosion is concerned). No soldering, use heavy clamps instead. Coat with some kind of noncorrosive 'goop'. Bury it deep enough so the lawn mower doesn't get into it. when you think you have enough metal in the ground, add another mile...
'Doc

PS - If you're going to use 136 Khz, make that 10 miles.

Also available from some branches of Wickes and B&Q Warehouses.

Not had any problems purchasing from electrical wholesalers as I fitted a shower for one of the daughters over Xmas and decided to put in one of the pull cord switches for her to isolate the shower - purchased this week (post 1/1/2005) from one of the larger suppliers with no questions asked.

Maybe it's the installation and not supplying that is under question - though typically our government bring in a silly law such as this - while they know that there is no right of entry to inspect.

David.

The problem arises when you try to sell your house. A prospective
purchaser's solicitor will ask for the certificates for any work you
admit to having been done post Jan 1.

Michael,
The TV antenna will probably help your reception. Try
the center conductor on the radio's terminal, or short
both inner/outer conductors and try that. Use whichever
works best. Inside/outside the house won't make as much
difference in what you hear as how high the antenna is.
'Doc

PS - Alternate method. Tie rock on end of a long piece of
wire. Throw rock over roof. Watch out for windows.

"Part P" doesn't stop DIY electrical work but such work MAY need to be
inspected. In fact, some level of inspection has always been imposed- the
electricity supply company does a check before connecting the "meter tails".

I admit to mix views on Part P, unnecessary red tape for those of us who
either know the correct way to do things, or are prepared to learn them, but
it is protection from those who believe in polarised resistors ;-)

I admit I would like to learn but prefer to spend my time doing other things - and admit that the house here is quite safe as we've had few electrical additions done apart from outside lighting. Everything else 'plugs in' so is not covered by the new regs.

> but
> it is protection from those who believe in polarised resistors ;-)

That was a low punch Brian - especially on a day when the design for the latest ground-breaking reinvention of the wheel in radio form is being proposed and discussed.

Sadly - like a plane with no engine - it won't ever get off the ground.

David.

Sorry but nobody is perfect.

Seriously, I still quote the (in)famous line about knowing one end of a
resistor from another in training courses. Always gets a laugh and, as you
probably know, a little humour in a lesson works wonders.

>Sadly - like a plane with no engine - it won't ever get off the ground.

In this case I think train not leaving the station as the signals don't work
is more appropriate.

==========

A ground connection is unnecessary with a dipole, whether the feedline is coaxial or twin wire. You are not mains operated or running a kilowatt..

A single earth spike is useles for a ground connection whatever the circumstances.

If it makes you feel safer, while sitting on your parkbench, you could connect the ground terminal on your transmitter to a 2-feet long earth spike via a 3-feet length of 18-gauge, flexible, multi-strand, plastic insulated wire.

Don't forget to take an umbrella with you!

Reg.

Simple Gareth, buy a scam mast, less than 12 foot tall so no planning
problems. even Liz might approve...
Or you could try an underground dipole, perfect for inter G on the lower
bands, No RFI and a nice quiet receive. Even in your 70 foot garden you
should be able to fit an 80M dipole in a straight line.

There is also a commercial 'roll out' antenna about. I'm sure someone
competent with a model engineering workshop could emulate it.

I've used the flat metal tape from a retractable tape measure in the past
for antenna elements- this could be the basis of a 'roll out' design.

The discs have a higher dielectric constant than the air. There is
therefore an increase of capacitance where there are (so the Zo dips
slightly).

As the discs are located at regular interval, where this spacing is one
wavelength, the repetitive higher capacitance adds up in parallel
(although buffered somewhat by the losses loss of the cable). The effect
is to produce a sharp suckout at the frequency of that wavelength (and
at multiples thereof). This effect is also referred to as 'Structural
Return Loss' (well, it's one of the causes). It sets the maximum
frequency at which the coax can be used.

The closer the spacing of the discs, the higher will be the suckout. If
the spacing is zero, the frequency will be infinite. However, you will
have just invented solid dielectric coax!

Ian.

> problems. even Liz might approve...

Not so, GPDO 1995 states that structures (masts and antennas) under 3m (~9'9") do not require planning permission, if sited at least 2m (~6'6") from any boundary, and at least 5m (~16'3") from a neighbours building. This is modified to the height of your ridge line (not chimney) visible by an average sized adult standing on the pavement at the front of your dwelling, if you have the structure attached to one of the existing walls of your property (not the front wall visible from the pavement). Exclusions are made for non-commercial antennas that are similar in size to a Broadcast TV Antenna & Mast, which may be erected on the chimney (I've had a 2 ele 6m beam on a rotator excluded under this provision).

At my last QTH, I had no planning permission for a ground mounted Butternut HF9V, the Planning Enforcement Officer that made a visit, said that an application was not required as it was under 4m tall (~13'0")?!?

I'm still within the area managed by the same Planning Authority, ;-)

Nice idea, what about combining that with the feed mechanism from an old
printer. I was going to dump an old OKI microline printer, the feed motor is
a reversible stepper motor so should be PC controllable.

Sounds good.

I'd thought of using a similar motor for a remote ATU.

I asked two simple questions out of curiosity: Has anyone
else ever noticed those taillights? & What would be the
advantage to that design? I finally got an answer to the
second question. Nobody else has reported seeing them but
they definitely exist. I suspect you still don't know what
I am talking about.

Yes I have seen these taillights. According to a news article about them there is a significant difference in how fast the new lights work compared to the older conventional lamps. One time I was following a truck that had diode lights on its trailer and conventional lamps on the tractor. There was a very noticeable difference in the two tail lights. The diode lamps were full on while the conventional lamps were still thinking about glowing. Supposedly this converts to about 17 feet difference at 55-65 miles per hour on the highway.

Never, ever use "Grease" (or any other lubricant/protectant) in an electrical connection for RF. Grease is a dialectric (so is silicone) and it will ensure you have practically no electrical connection at all.

There are copper and other metal-alloy pastes available for making mechanical lightning protection and RF connections. They are the only thing that should ever be used to make up mechanical joints. If you don't have them, make the joints dry and leave them that way. Copper oxide (normally green) that forms outside of bare copper from oxidation is conductive and causes very little difference in conductivity. Aluminum oxides and carbon steel rust are not very conductive, although not much different than poor soil that most radials are buried in.

Sorry, I don't know the answer. I operate my W2DU choke into close
to a pure resistance that varies between 28 ohms and 90 ohms. I
once measured the temperature of a #2 iron-core 4:1 commercial
voltage balun and got no appreciable temperature rise under varying
conditions but I don't know what conclusion can be drawn.

How to operate your all-HF-band dipole with a purely resistive
load of 28-90 ohms is described on my web page below.

Hi David, I'm not talking about conventional LED taillights. I'm
talking about LED taillights that are pulsed and maybe pulse-width
modulated between the taillight function and the brakelight function.
This seems to be something new on maybe one manufacturer's 2005
models. They may have a 1/3 duty cycle for taillights and a 2/3
duty cycle for brakelights, or something akin to that. It's a
mystery to me that I am trying to solve.

Some lights on towers and some roadside warning lights are pulsed on
and off at a ballpark rate of 100 Hz. If you sweep your eyes from
side to side, these pulsed lights appear as a dotted line in your
vision. That's the kind of taillights I am talking about. If you
sweep your eyes from side to side, the trail they leave on your
retina looks something like this:

Still is in the UK. Also I assume in the USA, one of my cars was made in the
USA and came with grease on the terminals.

> power simply heats up the ferrite.
> Ian.
==========
Ian, both your understanding and experience of how a balun works are limited. But don't be disheartened - you are in good company! ;o)

They are not simple transformers. The windings are in fact transmission lines consisting of a pair of wires running in parallel, either coaxial or balanced-twin - it doesn't matter which although balanced-twin is slightly more efficient and physically more easy to construct.

Their full name is "Transmission Line Transformers".

They have a wider bandwidth and a higher HF response than ordinary primary-and-secondary HF transformers. This is because the normal capacitance between turns and between windings is incorporated in the transmission lines instead of being directly in shunt with winding inductance.

They are inherently very low loss devices because there's only short lengths of high-conductivity copper involved.

In theory, there is no loss in the ferrite core because the currents in the transmission line wires flow, adjacent to each other, in oposite directions and the flux cancels out in the core. But cancellation is never completely perfect and HF-quality ferrite core material should be used. However, LF grade materials found in the junk box often work quite satisfactorily.

Cancellation is better with coaxial lines than with balanced twin but this is hardly a matter of importance. Ferrite rods require more turns to achieve the same inductance than rings at the low frequency end.

The ordinary inductance of the windings considered as single wires, in conjunction with the nominated terminating resistances, sets the low frequency response of a balun transformer in the usual way.

The high frequency end of the range is limited by the physical length of the line winding. Line length should be small in relation to the wavelength along the line. Upper frequency response and ratio begin to fall off when line length exceeds about 1/8 or 1/10 of a wavelength at its own velocity. Not free space velocity. This allows a frequency range of 1.8 to 30 MHz on a core of ordinary proportions with permeability in the range 200 to 400.

The performance and behaviour of an X-to-Y ohm balun, as with ordinary transformers, goes haywire if it is not operated between its designed-for resistances. Or at least resistances in the right ball-park.

Hence the futility at HF of using one between a multi-band antenna and any sort of transmission line or tuner. The range of impedances to be covered is even greater than those listed by our good friend Cecil.

A choke balun, a single short length of transmission line wound on a ring or rod, is a different kettle of fish. Its range of impedances is unlimited.

Reg, G4FGQ

Hi Ian,

In a current BalUn it is the Common Mode current that is absorbed by the BalUn as a choke (one purpose of two purposes to use it). The current BalUn is designed to add R rather than X to the Common Mode path (although, any additional X that comes down the pike is not shrugged off). Thus the product of that current and that resistance is heat. However, if you have a sufficient R, it snubs the I before you get to many Watts. A string of 20 beads can present upwards to 1000 Ohms resistance, but I wouldn't try to dissipate more than 20W throughout.

Now, as to efficiency. I presume the load is a nominal 50 Ohms, and that it is paralleled by that choke's 1000 Ohms. If we were in a condition where that same 1000 Ohms were dissipating 20W then it follows that the load is dissipating 400W. This is about the time when some Hams begin to tear their hair and fulminate at the BalUn (which is doing its job faithfully) rather than asking themselves the question:
"why is my antenna system trying to pump
that current down the transmission line?"

If they solved that question, then they would have more power available for their intended load. Others who would have reflected on that question naturally, they would have shrugged their shoulders and figure chasing that last 5% efficiency exceeded the small price they paid for the BalUn - which was working quite well.

Now, consider if that BalUn were to suddenly vanish. The same current which formerly saw 1000 Ohms, would see none. We can all work out the equivalent resistance of 0 Ohms paralleled to the intended load of 50 Ohms to observe where the power would eventually go. This is so extreme as to be absurd (or at least rare). Such a radical possibility necessarily presumes a rather disastrous implication in the state of the antenna's design - or damage.

However, none of this actually answers your question about "wrong impedances," but it does respond to the worst efficiency you could expect. By and large, when you are in the middle-to-near fringes of

the BalUn's operational range, efficiencies are exceptionally high (95% to 99+%). Whatever power that is lost to improper matching occurs in far greater abundance elsewhere.

Sounds like when he actually saw it, he realised it wasn't worth bothering about after all. Since he couldn't change the law for you, he re-valued the metre instead.

Actually Planning Officers have more discretion about "minor developments" than they will readily admit to. By going in for an informal chat, and taking along some mocked-up digital photographs showing what the proposed antennas would look like, I got a letter formally stating that my small crank-up mast and VHF yagis would not require planning permission.

The Planning Officer came out with a big multi-part ring binder (something along the lines of "How To Become A Planning Officer In 26 Weekly Instalments"). This had a whole chapter on amateur radio antennas, including photos of masts and antennas that had received planning permission, and even bigger ones that had gone through on appeal. After he had compared those with my own modest proposal, he became much more co-operative.

Your experience may vary, but an informal preliminary chat with the help
of some mocked-up images can never do any harm.

I use a 4:1 balun under such conditions. I use it simply to make my autotuner happy (which makes bandhopping easier). I have run extensive tests with the balun in and out on the HF bands and have yet to find anyone on the other end who could tell a difference.

>My understanding (and limited experience) is that most of your
>power simply heats up the ferrite.

My KW rated balun does get warm, even at 50 watts on some bands.

Of course tuners can also eat up considerable power on large mismatches. If you want (or need) a simple antenna system to work on all bands then you will likely have to absorb some loss no matter how you do it to get there. And the reason many don't have a big problem with this is even if you do lose *half* you power, that's still not a real big difference on the S meter at the other end...

Dear ml,

Not a bad idea. However, consider finding a chain link fence and tying your ground post to one of the chain link fence posts. Do not allow the ground wire from the rig to the earth exceed 1/12th wavelength at your frequency of operation - otherwise you will be elevated slightly above ground and other complications will begin to take place as you get closer and closer to 1/4 wavelength. At 1/4 wavelength you have an open circuit between the rig and the earth - which is real bad.

Note that even tho you are using a dipole, there will be RF coming down the outer shield of the coax which will find its way to earth one way or another. You prefer it not to be through the body.

Guys, the last time I checked, this was not rec.car.battery. We're talking about antennas and RF, not DC connections to your car battery. Using grease, even outside the made connection, will eventually penetrate the spaces. Maybe this doesn't matter to the 50-100w user, but it matters to high power connections, the most notable of which is lightning.

I may have missed something here but in my case I only have a 1/2 acre
'clear' under my tower. Because of the limited area
I chose to use a grid system of insulated solid wire an inch below the
surface with spacing of 3 feet per side of the grids.
I then removed insulation ar cross over points and crimped the wires
together, the crimping then made it quite easy for the solder to flow.
Tree roots have pushed up the wire in a couple of places but the rest is
unseen. I don't do to much work with verticals so I can't comment on the
sutability of this type of ground and have not read anywhere of any
comparisons to the normal radial
type ground especially for use over ALL of the amateur bands.
Food for thought. Judging by the number of responses recieved by the poster
there is a whole bunch of knoweledge out there on how to mess up your lawn
(yard over here)
P.S. get a mechanised pizza cutter to make the wire slots and place it on
the wheel of a wheel barrow so as not to alarm the neigbourhood
Cheers

If that Ian's garden is anything like this Ian's, in some directions he will probably be forced to lay down fewer and shorter radials than he'd like, and he may try to make up for that by overdoing it in other directions.

He'll probably give up when his back gives out... and still trying to work out exactly what you meant by "necessary".

>Is Sloan's Liniment still available?

Yes, the very approach I'm considering for two masts in the garden, one at 20ft to support one end of a 180ft doublet, and the other at 30ft to support some VHF/UHF antennas, a 2.4GHz fixed dish towards an VHF NFD Contest Site (line-of-sight at 23Km!), and I'm also considering another Dipole or Inverted-V for HF.

The 20ft mast will shadow an existing BT telegraph pole (had thought about using it!), and shouldn't be a problem in terms of planning or interference (well my telephone isn't connected to it), but the 30ft mast will have to be a wind up design as I want to experiment, and because I'm a long way down the rear garden, it could be 60ft tall and still wouldn't be seen from the pavement at the front of the house. 30ft or 40ft would be ample here as I'm on a hill anyway, and shall only initially be using two small beams on a rotator, for 2m and 23cms.

Art, you're a genius!

SM2CEW's website describes a radial plough which attaches to the back of a tractor, and can lay a full-sized Top Band radial in 2 minutes. I had been lamenting the lack of a Volvo tractor (or the space to lay such long radials) but a blade attached to a wheelbarrow might just do it... or even to the lawn mower.

Not if you make the electrical connection first, and then coat with
grease.

You wouldn't paint the radials ends and then make the joint.

OTOH, perhaps you would.

PS: Paint can be a dielectric too......

Thanks for the injection of sense, Brian. As I say elsewhere, you
wouldn't paint it first then make the connection.

OTOH, perhaps that's whey no-one has heard Bean on the bands.....

524. J pole vs ground plane? Which better for base?

Newsgroup: rec.radio.amateur.antenna
Date: 2005-01-09 23:16:39 UTC
From: stryped@hotmail.com
Message-ID: <1105312599.482663.54080@c13g2000cwb.googlegroups.com>
Source record: 83912

I am wanting a base antenna to put atop my tv tower. I am considering building a j pole or a ground plane. Which in your opeiong is better and why?

Also, most ground planes I see are for 1/4 wave. Is a 5/8 wave better? What about a full wave?

I plan on using 2 meters and maybe 440.

525. Ice storm - rebuilding antenna farm - advice needed!

Newsgroup: rec.radio.amateur.antenna
Date: 2005-01-09 23:19:48 UTC
From: Ken Bessler <kg0wx@NOSPAMyahoo.com>
Message-ID: <n_iEd.17594$ph.13027@okepread01>
Source record: 83913

I lost all my antennas this week in an ice storm. Shows how bad my decision was stringing them up in the trees.

Oh, well - it's just wire... Luckily, the lightweight cord that was holding up one end of my 160/80m trap dipole failed before the trees did so when the branches came down, there was no damage.

Now - to the rebuilding! I don't operate much above 40m and my B&W rotary antenna switch was destroyed. I'm also left with much fewer branches to hang dipoles from.

Before, I had plenty of trees, coax & wire. I had single or dualband (fan) inverted V's for each HF band. Now that's out - no antenna switch and no tree space for more than 2-3 antennas.

Which would be better - adding 40m traps to my 160/80m antenna or leaving it as is and buying a tuner? How well would a 160/80 trap dipole up 25-30' work on the higher bands when used with a tuner? When I speak higher bands, I'm referring to 40 to 6 meters. I'll add a cushcraft MA5B and V/UHF antennas later.

The current antenna is about 220' of #14 wire with 3.9mhz traps. The traps are 8.33 turns of RG58 around a 3.5" form. The antenna is fed directly with 60' of RG58 and so far has proven to be a good performer on 160 & 80 meters. It has low SWR at 1.88 and 3.9 mhz.

Any ideas, folks?

Ken KG0WX

High SWR does sort of mean loss. It is just that with ladder line the loss is very low compaired to coax. If you have almost no loss and multiply it by 10 due to high swr you still have very small loss. If you start out with coax and have a much larger loss to start with and multiply it by the same number , you will have much larger loss.

Plus, of course, the issue isn't so much the power as the current when
thinking of high resistance connections. The cranking current drawn via a
car battery terminal is around 100A. If the grease ingress caused a high
resistance connection, the car wouldn't start. In practice, ungreased
connections tend to 'go high' due to corrosion.

A radio telescope is a receive-only device. It is incapable of rendering anything sterile.

A radar telescope--using a dish--can be dangerous and the EIRP can be megawatts. In this case, a number of health dangers apply. Fortunately those most likely to be exposed are the best informed, and I am not familiar with a single case of dangerous exposure.

SETI has nothing to do with this.

73,

Ken,
Sorry to hear about your ice storm.
Can you make the antenna 240 feet long? I use a centerfed dipole with w7fg
600 ohm balanced feed that long. It tunes well on 160 to 10 meters with a
Ten Tec 229 tuner and balun. Of course the antenna pattern may not be what
you want.

I use #10 copperweld, 750 lb Dacron supporting rope, and 5 1 gallon
containers of anti-freeze on the pulley end.

Regards,
Ed, N5EI

That is funny. But since this has now become rec.batteries.car (just kidding):

The reaction from battery acids, air and dirt are minimized with grease. But mechanics who grease the inside of the cable-clamp and outside of the battery post *before the connection is made* are not helping the electrical connection - they're applying preventative maintenance for idiots - who never clean their battery posts. Conductive paste is much more expensive than grease. Those who know what they are doing use the former. Conductive paste is specified in US Lightning protection (NEC-70/NFPA-780), and grease is not allowed to be used in any mechanical connection there. Back to antennas for a moment, we all know that grease (or conductive pate) does not provide waterproofing of any kind. And most of you will accept that grease is a dialectric, not a conductor. But after making a mechanical joint with conductive paste (ensuring no air enters the joint, and conductivity remains per the connected materials), and proper waterproofing is applied, you have a safe and maintenance-free joint that will last for years. Or it would anyway, if the same codes didn't require you to expose and mechanically tighten every such joint once a year. That's why the expensive exothermic (welding) of all grounding electrode conductor joints becomes a savings in the long run. Unfortunately that is never practical along rooflines up on masts and towers. So those mechanical joints must provide as little impedance as possible, and survival of the equipment depends on this.

Because all transmitter antenna radials automatically become a part of the lightning protection system, the materials used should be the best you could afford, not the cheapest you can find. And the connections should likewise be the best possible. The transmission system will be more efficient, and safer.

I just checked one of my catalogs from a restaurant supply store
(Bridge Kitchenware in New York City), and I notice they sell pizza
cutters with wheels as big as 5 inches in diameter. If you used hose
clamps to attach the handle of a pizza cutter to the end of a broom
handle, I bet that would make a dandy lawn slit cutter for laying
radials.

>even stranger was the same equation as above but run for coax,

Hi OM,

Line loss is only specified into a matched load (equal to the Zo of the line). Into other loads, you have to calculate/measure it for yourself (SWR multiplies line loss).

Loss is in the resistance of the copper wire. The copper wire of the center conductor of coax is the limiting factor. Except for the largest ($$$) grade of coax, that copper center conductor is usually smaller than the average (ï¿½ï¿½ï¿½) grade of twin lead's conductors.

Given the same SWR, you probably can now appreciate why one is less lossy than the other. If your twin lead still has too much loss, replace it with larger conductor (still ï¿½ï¿½ï¿½ at most bulk wire outlets).

Well, the Planning Enforcement Officer must make a determination of
which side of your house is the front, and view the house from standing
at least 6ft from your boundary.

>
> Can I insist that my neighbour removes the two 80 foot oak trees he has
> grown in his garden?

Possibly not, but you may erect an 80ft mast and almost certainly gain
approved planning, since stating that he has two 80ft trees next door
will allow you to maintain that the visual impact of your tower/antennas
various, will not be over-powering to the local area. ;-)

It's not normally grease, it's vaseline, which is conductive. I don't know
how vaseline behaves at RF, though. Maybe not too well?

>replace it with larger conductor (still ��� at most bulk wire
>outlets).

It's not just the wire gauge. Twinlead and ladder line and open-wire
line have a higher characteristic impedance than coax. Assuming a
matched source and load, the ladder line will carry any given amount
of power with a higher voltage across the line, and a lower current
through the line, than a coax will.

Losses are proportional to (I^2*R), and so you can decrease the losses
by either decreasing the resistance (larger wire gauge), or using a
higher-impedance matched feedline (lower currents).

I'm sure you've read these letters asking you to send $1 to six different addresses. Putting your home address or mailing address on the internet can be risky, but through PayPal all you have to provide is your email address. It's safe and easy. Just go to www.paypal.com and set up your FREE account! No credit card is needed. I am not a gullible person and have never trusted things like this, but I gave it a try. Hey it's only $6. I figured at least 6 people would respond out of the millions of people that use the internet. You should give it a try too! You have nothing to lose, and thousands to gain! Read on for the letter that I found (of course, I added my PayPal e-mail on #6)...

HOW TO TURN $6 INTO $6,000+!!! THIS REALLY CAN MAKE YOU EASY MONEY!!! IT WORKS!!! BUT YOU HAVE TO FOLLOW IT TO THE LETTER FOR IT TO WORK!!!! A little while back, I was browsing through newsgroups, just like you are now and came across an article similar to this that said you could make thousands of dollars within weeks with only an initial investment of $6.00! So I thought, "Yeah, right, this must be some kind of scam" but like most of us, I was curious, so I kept reading. Anyway, it said that you send $1.00 though PayPal to each of the emails stated in the article. You then place your own email address in the bottom of the list at #6, and post the article in at least 200 news groups. (There are thousands) No catch. That was it. So after thinking it over, and talking to few people first, I thought about trying it. I figured what have I got to lose except $6.00, right? Like most of us I was a little skeptical and a little worried about the legal aspects of it. It follows the same regulations as the "mailed chain letters, which according to the U.S. Post Office (1-800-725-2161) is indeed legal! Then I invested the measly $6.00. Well GUESS WHAT!!? Within 7 days, I started getting money in my PayPal account! I was shocked! I figured it would end soon, but the money just kept coming in. In my first week, I made about $20.00. By the end second week I had made a total over $1,200.00!!! In the third week I had over $10,000.00 and it's still growing. This is now my fourth week and I have made a total of just over $36,000.00 and it's still coming in rapidly. It's Certainly worth $6.00. I have spent more than that on the lottery!! Let me tell you how this works and most importantly, why it works? Also, make sure you print a copy of this article now, so that you can get the information off of it as you need it.

$$

REQUIREMENTS: You must have a confirmed PayPal account. If you do not have a PayPal account you can go to www.paypal.com and follow the

instructions to set up a free account. In order to place the initial $6 into your account, you will have to confirm your bank account with PayPal (which may take a few days). PayPal is 100% secure and is used my millions of people world wide. Confirming a www.paypal.com account simply means (1) PayPal will first ask you to confirm the email you used to sign up your PayPal account by sending you an email with a link for you to click to that email. As soon as you click that link your email is confirmed. (2) PayPal will then make two small deposits into your bank account if you set up your PayPal account with a checking or savings bank account. Or PayPal will make two small deposits to your credit card if you set up your PayPal account with your credit card. Then after a few days (it takes up to a few days for these deposits to appear in your bank account or on your credit card statement) then after a few days you go back to the www.paypal.com website and sign in. Then you click where it says this account is not yet confirmed. A screen will pop up that gives you 2 boxes to fill in. You then enter the numbers of the 2 small deposit amounts (two separate 2 digit numbers) that were deposited to your bank account or credit card. Now you have a working and confirmed PayPal account and can receive payments.

$$

[STEP 1]
Send, though PayPal, $1.00 to each email on the below list. Make the subject of the payment "Email List" and in the comments, write "PLEASE PUT ME ON YOUR EMAIL LIST." What you are doing is creating a service by this - and best of all you are not giving your address to anyone you do not know. THIS IS ABSOLUTELY LEGAL!! YOU ARE CREATING A SERVICE. Here are the latest PayPal e-mails on the e-mail lists:

#1)brittany...@excite.com

#2) mth...@renc.igs.net

#3) Mishav...@aol.com

#4) nike31...@aol.com

#5) careent...@hotmail.com

#6) jjrvn...@hotmail.com

www.paypal.com

Subject of Payment: ***Email List***

Comments: ***PLEASE PUT ME ON YOUR EMAIL LIST***

[STEP 2]
Now take the #1) email off the list that you see above, move the other addresses up one (6 becomes 5 & 5 becomes 4, etc) the put YOUR email address (the one used in your PayPal account) as #6) on the list. **MAKE SURE THE EMAIL YOU SUPPLY IS EXACTLY AS IT APPEARS IN YOUR

PAYPAL ACCOUNT**

[STEP 3]
Change anything you need to, but try to keep this article as close to original as possible. Now, post your amended article to at least 200 newsgroups, message boards, etc. (I think there are close to 32,000 groups) All you need is 200, but remember, the more you post, the more money you make - as well as everyone else on the list! In this situation your job is to let as many people see this letter as possible. So they will make you and me reach!!!! You can even start posting the moment your email is confirmed. Payments will still appear in your PayPal account even while your bank account is being confirmed.

$$

DIRECTIONS ON HOW TO POST TO NEWSGROUPS/MESSAGE BOARDS.

[Step 1]
You do not need to re-type this entire letter to do your own posting. Simply put your CURSOR at the beginning of this letter and drag your CURSOR to the bottom of this document, and select 'copy' from the edit menu. This will copy the entire letter into your computer's temporary memory.

[Step 2]
Open a blank Notepad file and place your cursor at the top of the blank page. From the 'Edit' menu select 'Paste'. This will paste a copy of the letter into notepad so that you can add your email to the list.

[Step 3]
Save your new Notepad file as a .txt file. If you want to do your postings in different sittings, you'll always have this file to go back to.

[Step 4]
Use Netscape or Internet Explorer and try searching for various newsgroups, on-line forums, message boards, bulletin boards, chat sites, discussions, discussion groups, online communities, etc. EXAMPLE: go to any search engine like yahoo.com, google.com, altavista.com, excite.com, then search with subjects like "millionaire message board" or "money making message board" or "opportunity message board" or "money making discussions" or "business bulletin board" or "money making forum" etc. You will find thousands and thousands of message boards. Click them one by one then you will find the option to post a new message.

[Step 5]
Visit these message boards and post this article as a new message by highlighting the text of this letter and selecting 'Paste' from the 'Edit' menu. Fill in the Subject, this will be the header that everyone sees as they scroll thru the list of postings in a particular group, click the post message button. You're done with your first one! Congratulations! THAT'S IT!! All you have to do is jump to different

newsgroups and post away. After you get the hang of it, it will take about 30 seconds for each newsgroup! **REMEMBER, THE MORE NEWSGROUPS AND/OR MESSAGE BOARDS YOU POST IN, THE MORE MONEY YOU WILL MAKE!! BUT YOU HAVE TO POST A MINIMUM OF 200** That's it! You will begin receiving money within days! **JUST MAKE SURE THE EMAIL YOU SUPPLY IS EXACTLY AS IT APPEARS ON PAYPAL.**

Have fun!

The more I think about it, the more it seems likely that a common-mode
wave travels down the outside of the braid until it encounters the
choke impedance and is reflected, at least partially. That would
create common-mode standing waves. When the weather clears up, I
think I will see if the common-mode current goes through a maximum
and minimum up and down the coax.

Assuming the auto LEDs have three states, off, taillight, and
brakelight, that is taking data from three different input
sources and combining them into one time-shared output. That,
my friend, meets the definition of multiplexing even if only
trivially.

Bob
The idea is to not mess up the lawn PLUS controlling the depth of the cut.
When the slicer is on the wheel the main weight of the barrow is directly
over the slicer thus making it easir to slice the lawn at a controled depth
reducing the possibility of jamming at a lower depth.
The whole idea is not to mess up the lawn and by taking some flower pots
from one end and changing them over at the other end will look like you are
working hard in the garden and shaming the neigbors in front of yjeir wifes.
Cheers
Art
I might add I used a tractor system when I did mine which also inserted the
wire but you just don't mess with an English lawn or you will lose the
impression of perfection
and where wifes are known to use treezers for the final touch.
Reminds me of a story where a yank admired a particular lawn
at some notable tourist site.
He asked the ground keeper how he could duplicate it when he got home,
Certainly the groundskeeper replied but firt you must start the lawn several
centeries ago!

> the resistane of the coax?
>
> boy i am mixed up

The losses at HF are primarily proportional to current. Current is
inversely proportional to the characteristic impedance of the feedline,
i.e. I=V/Z0

So I=V/450 is nine times lower than I=V/50. Even with an "SWR around
5" on the ladder-line and 1:1 on the coax, V/450 is probably lower
than V/50. In fact, for the current to be the same on 450 ohm ladder-
line and 50 ohm coax (for the same power) The RMS voltage on the
ladder-line would need to be nine times the RMS voltage on the
coax. So you see ladder-line can tolerate a relatively high SWR
before its RMS current equals the RMS coax current.

If it isn't in the the current path (ie between the mating surfaces) and
also not acting as an unwanted path (eg between the earth clap and the
antenna), does it matter? OK, you may get some local absortion of RF energy,
but how much grease are you going to use? Not enough to absorb much RF and
the mass of grease (or vaseline) will be far less than other unquantified RF
conductors and absorbers in the vicinity.

You need to look at things like this in the context of the problem.

First, let's agree on nomenclature; a radio telescope is a receiving device only, it is not an emitter. Feel free to coin a new term for a highly directional, high power emitter used for astronomical research.

RF exposure can cause many things, from nothing sensible to boiling to carbonization to vaporization. It all depends on the RF power, the absorption and the time of exposure. Absorption is dependent on frequency and conductivity of the sample. Heating is dependent on the power, the absorption and the ability to transfer heat from the sample.

For instance, 14 GHz exposure will result in most radiation reflecting off a human body; move the exposure to 2.4 GHz, and the effective depth of heating will be several inches into the tissues. Move down to 960 MHz, and you will get even deeper heating. (Consider why industrial microwave ovens are at 960 MHz.)

Some body tissues are more exposed to RF, and, having only modest blood circulation, have a poor ability to transfer heat. Assuming you are male, those tissues at risk would include your earlobes, fingertips, nose, corneas, elbows, penis, scrotum, testicles and toes. Your earlobes, nose, fingers and scrotum have good circulation, so the blood cooling helps to protect them. Your toes are usually electrically close to the ground, and in a region of lower power density. Your penis is also well cooled and poorly exposed, unless RF exposure gives you a woodie. And who cares what happens

to your elbows? So that leaves your corneas and testicles as the most vulnerable tissues.

Canadian Safety Code 6 is a well-written document that will also teach you a lot about RF emissions, RF measurement and biological effects. It's limits are based on old ANSI C95.3-1991 work, which has been codified as IEEE STD C95.1-1999. The USA FCC also uses the IEEE standard. Both the IEEE and ANSI want to charge you for access, but Industry Canada courteously provides a free download at:

http://www.hc-sc.gc.ca/hecs-sesc/ccrpb/pdf/99ehd237.pdf

Thanks, Canada!

So we see that RF can do essentially nothing, it can sterilize, it can cook, it can kill, and it can destroy. It's all a matter of power, frequency, target and time.

True. But in your design the antenna wire will be carrying serious
tension loads in addition to its own weight, and you would need aerial
components suitably rated for this.

Jack Painter wrote:

[...]

Jack is absolutely right about grease being non-conductive! It only keeps air and moisture out of the areas where the metal is already touching.

The same is true of the special conductive greases - the particles of metal provide the conductivity, and the grease only serves to seal around the contact surfaces.

Let's drive a stake through this stupid urban myth. Vaseline (pure soft petroleum jelly) is a mixture of hydrocarbons, and is a very close relative of polyethylene, polypropylene, beeswax and other well-known insulators.

Still don't believe it?

Creak... stomp stomp stomp... medicine cabinet... jar of Vaseline... stomp stomp stomp... multimeter... 20 megohm range... test prods... WELL OF COURSE it's bloody non-conductive!!!!!

Two touching greased surfaces still read >20M until you grind them together and force the grease out. And unless you DO force two greased metal surfaces together, they will be almost perfectly insulated from each other!

[...]

Just one further comment on Jack's posting:

>Because all transmitter antenna radials automatically become a part of
>the lightning protection system, the materials used should be the best
>you could afford, not the cheapest you can find. And the connections
>should likewise be the best possible.

In principle that is correct, but heavy-duty radials are not cost-effective for ham installations, because there are so many of them (even in a small system). Also, heavy-duty radials are not necessary for the main purpose, which is RF grounding for normal operation. For a ham installation, it seems much more realistic to install enough ground rods to qualify as a lightning ground in their own right (as if there weren't any radials at all). Then you can treat the radials as being purely for RF grounding. They will of course contribute to lightning grounding, but you don't have to rely on them for that purpose.

We're moving house, so I am just about to tear up the radial system here - and also pull out the 8ft ground rod that goes 5-6ft into groundwater. The next QTH will have much more space, so this discussion comes at just the right time.

TOO MUCH certainly can, and of course there are many documented cases.

It's Thierry's use of "we know" that bugs me. Does anyone actually
know of any case where:

People have been working in (inside) a radiotelescope dish
AND
The transmitter has been on (most radiotelescopes don't even have one)
AND
They have become sterile?

No, I thought not. That's because it's pure techno-folklore.

More techno-folklore.

The only heating power available is the power supplied up the feedline.
"Magnification" by the antenna is irrelevant, and EIRP figures only
serve to scare people.

Actually, the exact opposite is true. RF hazards are a function of power density (mW/cm^2 or W/m^2). The higher the antenna gain is, and the higher the far-field EIRP, the larger the aperture area must be and therefore the lower the power density becomes.

The most dangerous antenna is the smallest, for example, an open-ended waveguide or a small horn. That is because all the available power is concentrated into such a small area. Looking into an open waveguide is like looking into the barrel of a gun - you don't do it until you've made darn sure about the other end!

But if you take that horn outside and mount it on a big dish where it's hard to come anywhere near, it is immediately much safer. And the larger the dish is, the smaller the RF hazard becomes.

Bottom line: "EIRP" and "RF hazard" don't belong in the same sentence - except this one.

Jack, many thanks for your informative post, it was certainly an
interesting read, and deserves a response.

I'd like to quote what Brian Reay said in reply to another poster on
this topic. He said "If it isn't in the current path (i.e. between the
mating surfaces) and also not acting as an unwanted path (eg between
the earth clamp and the antenna), does it matter? OK, you may get some
local absorption of RF energy, but how much grease are you going to
use? Not enough to absorb much RF and the mass of grease (or vaseline)
will be far less than other unquantified RF conductors and absorbers
in the vicinity.

You need to look at things like this in the context of the problem."

Now I don't doubt that everyone who has contributed is right in their
own way, but look at the wider problems of the Radio Amateur's
vertical antenna that demand attention. Only having one element, it
has to work against something, which in this case is the ground or
earth. To work with some efficiency it has to make good contact with
said ground or earth, and I did some calculations elsewhere showing in
simple terms how this can vary with the ohmage of the earth path.
Hence the advice about radials wires, cost, corrosion, and all the
other things.

But this antenna has to live outside and cope with wind, rain, snow,
ice, hail, frost, dog pee, etc, the whole nine yards, and this has to
be taken into account in the design and construction phases. What you
wind up with is a compromise, and everyone's choices will likely be
different. I doubt that anyone puts up a vertical antenna designed to
cope with a lightning strike - and very many antenna designs (such as
balanced dipoles) might have either no DC earth path or only a
fortuitous one - or even a 1000 ohm resistor as a static leakage
path....it just doesn't feature as a major topic.

Just to illustrate the point about what is incorporated in antenna designs, we've had some bad weather here in the UK over the last few days. One amateur on here had his wire doublet aerial anchored in a tree, which blew over in the wind. It pulled his aerial along, together with the length of feeder to his radio. Result was everything on the shelf was pulled off onto the floor. So although this amateur had an off-the-shelf design of aerial, he had no snap-line in place that would have broken when the tree went over. I'll bet there wasn't much lightning protection either.....

It comes down at the end of the day to the art of the possible. While a storm-proof, lightning-resistant, non-corroding, highly efficient vertical antenna could be designed and constructed, it would cost a fortune, and at the end of the day you'd still have 'only' a vertical antenna - which anyway is not an all-round solution to working other amateur stations.

I myself had a vertical antenna for some decades, the earth system of which was constructed along the lines I mentioned elsewhere. It withstood everything thrown at it, including the 'great storm' of 1987 with hurricane-force winds. On those occasions when licensed amateurs used it, there was negligible fall-off in the aerial current over its life-span, which told me that the earth system was not deteriorating. In the end the 'maintenance' of this aerial consisted of an occasional spray of WD40 (shock, horror) - but when finally dismantled, *all* the mating connections were bright and tight....it served me well and I don't think I could have asked for more.

Hi, Evan:

Got one, but not NOS, simply "O", already mounted in a 3X4X5 aluminum box,
with 2 SO239s and 2 BNCs for r-f, and a 7-pin Amphenol connector for the
6VDC at about 1A relay coil
control signals. It's got that same gray-tan ceramic-like insulation as
the old Johnson coils, and it's about the same size as, or maybe a hair
bigger than, those non-latching relays you sold me a year or two ago.
Contacts are about 3/16ths, and they are silver. I can tell by the oxide
;o)

If you're interested, I'd trade it and $20 for one of those DPDT knife
switches you may still have.

Cec, its obvious even to a citizens bander that when the common-mode current and volts encounters the choke, or anything else, it is reflected. There's no need to risk your neck to detect it.

You won't prove anything anyway. Your particular antenna might not suffer from noticeable common-mode effects. And you can't deliberately inject a test signal at any place because it would upset circuit conditions.

Furthermore, the choke does NOT do what the old-wives say it does, ie., stop radiation from the line and prevent noise pick-up. It might even make matters worse. The choke merely shifts the volts and amps standing waves to other places along the line.

Have I upset the apple cart again?

Reg.

Dear ml

Here is the part that no on this thread has come right out and talked about, and it is the answer to what is bothering you.

If you have an IDEAL transmission line - that is, one with no resistivity in the conductors and no dielectric loss in the insulation, then the SWR can be sky high, but there will be NO LOSSES.

SWR is nothing more than an unfortunate summation of voltages and currents that cause the voltages and currents to look more like a roller coaster than a straight line. Voltages and currents do not necessarily multiply to give power. Sometimes they multiply to zero - when the angle between them is 90 degrees. And that's what you have when there are no losses.

OK?

What if you are trying to tune a ground plane for the aircraft band? I
mean, you cant transmit on this. I just want to listen.

|
|The discs have a higher dielectric constant than the air. There is
|therefore an increase of capacitance where there are (so the Zo dips
|slightly).

Okay, I guess this stuff doesn't use the compensation that I am
familiar with where either/or/both conductor diameters are modified to
account for the dielectric constant difference and the locations are
not at regular intervals.

Some of the missiles I've worked on used beaded coax at 10 Ghz.

|
|As the discs are located at regular interval, where this spacing is one
|wavelength, the repetitive higher capacitance adds up in parallel
|(although buffered somewhat by the losses loss of the cable). The effect

|is to produce a sharp suckout at the frequency of that wavelength (and
|at multiples thereof). This effect is also referred to as 'Structural
|Return Loss' (well, it's one of the causes). It sets the maximum
|frequency at which the coax can be used.

The "suck out" you refer to is primarily due to mismatch loss. For the case at hand (ham operation, i.e., a narrow-band system) I don't think this is an issue.

Wes

Judging from some of the assertions on the subject, some people consider
common-mode current to be a series circuit problem, not a distributed
network problem.

> You won't prove anything anyway. Your particular antenna might not suffer
> from noticeable common-mode effects. And you can't deliberately inject a
> test signal at any place because it would upset circuit conditions.

I'm running a G5RV right now. All I have to do to gin-up common-mode
currents on at least one of the eight HF bands is to remove the choke
at the coax to ladder-line junction.

> Furthermore, the choke does NOT do what the old-wives say it does, ie., stop
> radiation from the line and prevent noise pick-up. It might even make
> matters worse. The choke merely shifts the volts and amps standing waves to
> other places along the line.

I use a choke to reduce common-mode problems in the shack and it does
that apparently by causing reflection of common-mode waves back toward
the antenna which, as you say, wouldn't decrease feedline radiation
between the choke and the antenna.

> Have I upset the apple cart again?

Where does the common-mode power go? :-) If differential reflected
power can be almost 100% delivered to the antenna by matching, how
about common-mode power? What happens to the common-mode reflected
power when it gets back to the antenna?

> So, about any omni is as good as another?

Nope, he didn't say that. Stacked phased vertical elements,
as exist in repeater antennas, can offer a tremendous amount
of gain over a 1/4WL ground plane. I have an old Comet 2x4MAX
and the gain over a 1/4WL ground plane is amazing.

The Diamond NR22L for 2m, is 97" long and is two elements of
5/8WL each and thus will have about 3 dB gain over a 1/4WL
ground plane, about the same as an Extended Double Zepp.

He might be making the J-Pole one-wavelength long which would
indeed result in about 3 dB of gain but at a relatively useless
take-off-angle.

Hi Ian,

Even more remote is EIRP and nearness (EIRP demands the source appear
to be a point so that all phases from the reflector add to produce the
EIRP).

Another boner is that "a radio telescope is a receive-only device."
This bald statement would consign Arecibo to the ash heap of radio
telescopes because it has a 430 MHz radar system built into it. I
suppose by the same logic, a radar is a receive-only device between
pulses.

I suspect that he's comparing a standard half-wave-radiator J-pole to
a typical "ground plane" antenna (a quarter-wave monopole, with one
set of quarter-wave radials, possibly tilted downwards for an
impedance match).

The latter sort of antenna falls somewhat short of behaving like
a true infinite-ground-plane antenna, as the radials are neither
horizontal nor infinite in extent. If I recall correctly, the
radiation pattern will be tilted upwards from the horizon by
a significant amount.

The J-pole will be close to 0 dBd, while the "ground plane" will
probably fall a few dB short of that figure out at the horizon.

Further thoughts....

In order to be able to both release and then fold up the
antenna, a mechanism based on two tendons, not too
dissimilar to the human knee and elbow joints would be
required.

Consider the flexing effect of each of your fingers - one
tendon at the back and one at the front.

And in order to maintain good RF contact across the joint,
perhaps the use of braid recovered from coax cable?

The ï¿½-wave groundplane was developed by George Brown 1938. Here's a partial quote from his book:

"... In our initial experiments we found that only two horizontal rods (ground rods) functioned as well as four. Many people from the Broadcast Sales organization came by to view our tests and they always expressed doubts as to the ability to radiate uniformly when only two ground rods were used. To quiet them, we used four ground rods for a while, thus stilling the criticism. When the antenna became really popular, we did not dare confess to our ruse."

There you have it from the inventor of the antenna.

Interesting... although while I'd certainly believe that, as far as Georbe Brown could tell in 1938 two radials performed just as well as four radials, I'd imagine that there is a measurable and simulatable different between the two systems!

(Hmm... I know... how about... three! ground radials? :-))

A ground plane is an attempt to simulate the earth, with better
conduction, so the more radials the better.

Aside from longer life of the LED's, nothing that I can see.

I've seen, in two Semi trucks, alot of RF coming from the
taillights/brake lights/turn signals/reverse lights... a .01uF cap from
the positive lead to ground has solved the problems on more than one
occasion in both my Ford and my Peterbilt.

>
It isn't really helpful to think of it as "reflecting common-mode waves back". It is simply Ohm's law: a high series impedance reduces the amount of current that will flow.

Forcing a current minimum at one location on the feedline (usually right at the end of the coax) will change the current and voltage distribution not only on the feedline, but also on the antenna proper. The whole antenna-feedline system readjusts itself to take account of the fact that the choke impedance is there. This readjustment will also change the feedpoint impedance, so it's actually true that a balun will change the SWR of the antenna - it has become a different system that no longer involves the feedline.

Reg is right to say that the choke shifts the common-mode voltage and current standing waves to other places along the feedline. Depending on the location of the 'victim' equipment (TV etc) relative to those standing waves, the change can sometimes make RFI problems worse. Even so, a choke balun right at the end of the coax is almost always the right place to start. If it doesn't help, it may *still* make sense to leave it there, and try a second choke somewhere else as well.

A clip-on RF current probe can work wonders in showing you what really is happening.

I live in a "no antenna" gated community. So I use a vert. (removable) for 20 M. The radials are simply laid on the ground and they are insulated telephone wire. (I had plenty), they are twisted together at the base of the antenna and connected to the braid with an aligator clip. Real high tech here. But I get out all I want.(K.I.S.S.) All this with 100W and an old HW100.

It doesn't matter whether it's Arecibo or just an open waveguide, you cannot ever be heated by more energy than is being supplied by the transmitter.

The transmitter supplies all the available energy - there is no other energy source involved - and it all comes out of the feedhorn. If you're on the catwalk close to the feedhorn, and if there is enough energy, then of course you'll feel it.

But that interaction involves only the transmitter, the feedhorn and you. The dish and its gain have absolutely nothing to do with it. If the dish were completely removed, you would still experience exactly the same.

True for a bench circuit. Not necessarily true for a distributed
network. In fact, a choke that makes the outside braid of a
transmission look like an open circuit (best case), makes it look
like a short circuit 1/4WL back from that point. If the choke is
placed at an existing current minimum point, it will have little
effect.

Do you have access to a ARRL habdbook?? I see a very informative graph
on page 16-14 of the 1990 ARRL handbook that clearly indicates how
transmission line loss and VSWR are related.

Jerry

No, in most implementations, ground radials are very much attempting to simulate a solid, perfectly conducting plane under the antenna. Given enough of them, they do a reasonably good job.

> On another note, why are some of the radials bent to a 45 degree angle
> and some are not?

As you go to few and fewer radials, the 'pull' of the 'simulated' ground becomes 'weaker' in a sense and the radiation pattern of an antenna with horizontal radials tends to have its maximum at an angle significantly above the horizontal plane. By angling the radials downward, the radiation pattern is pulled back downward and the maximum radiation is again more or less horizontal.

(If you don't like this 'maybe intuitive to me and not at all to you' explanation, you can simulate an antenna with radials in, e.g., ezNEC and see what the actual results are...)

Pardon an ignorant sailor butting in here but I have a question about antenna material. I have been experimenting with home brew QFH antennas to receive 137.5 Mhz weather satellite images. I built one out of copper tubing that works great. I can get good pictures from Hudson Bay to Puerto Rico. Then I tried to duplicate it with stainless tubing to use on the boat. The two antennas and baluns are identical but the stainless version has less than half the range. Any suggestions on how to modify or tune it to improve reception?

Or, failing that, what effect would powder coating the copper one have?

Why not use a roll of wire netting and bury that.

Actually, Dave, what I should have written, is that Isaac Newton later provided the proof Galileo needed to support his hypothesis.

Further, it was to the Holy Office, at Rome, not to the Holy See, that Galileo presented himself.

Now, what is that proof of which you write?

There are a zillion remote weather stations all over the country.
Many are for specific purpose such as providing info for Fire weather,
snow pack levels, and as you have seen, stream flow guages for water
management and flood control. Some of the remote weather stations
(RAWS) can be seen listed at:

http://raws.boi.noaa.gov/rawsidx.html

Do a Google search on "RAWS" weather data. Also, stream flow
stations and remote snow pack stations can often be found on your local
State's water management department.

Bottom line answer to your question, YES, the data you probably
would like to see is available on the Internet.

> (Hmm... I know... how about... three! ground radials? :-))

Actually, for decades, I have built and used 3 radial ground plane antennas for 2M and for 440. I simply used brass welding rods and SO-239 connectors to construct them. The reason I used 3 radials.... I too was under the misconception that 4 were best, but I had a slight difficulty adding the 4th radials to my SO-239s so I stuck with three. Incidently, I found the best 50 ohm match was made when I bent the radials down about 45 degrees. They worked extremely well when properly tuned and stood up to some pretty heavy weather, too.

I have never asked when the tech was working on the system, original install or serviceing it. I have only stoped to check on him while at work. In the days of this we have to watch out for the homeland security.

He stated that it worked off of low oberting satatlites but as far as frequency range I never asked. Drive by and chck with a frequency counter and see what comes up. It will be all packet data, with short transmit times.

I'm sure you've read these letters asking you to send $1 to six different addresses. Putting your home address or mailing address on the internet can be risky, but through PayPal all you have to provide is your email address. It's safe and easy. Just go to www.paypal.com and set up your FREE account! No credit card is needed. I am not a gullible person and have never trusted things like this, but I gave it a try. Hey it's only $6. I figured at least 6 people would respond out of the millions of people that use the internet. You should give it a try too! You have nothing to lose, and thousands to gain! Read on for the letter that I found (of course, I added my PayPal e-mail on #6)...

HOW TO TURN $6 INTO $6,000+!!! THIS REALLY CAN MAKE YOU EASY MONEY!!! IT WORKS!!! BUT YOU HAVE TO FOLLOW IT TO THE LETTER FOR IT TO WORK!!!! A little while back, I was browsing through newsgroups, just like you are now and came across an article similar to this that said you could make thousands of dollars within weeks with only an initial investment of $6.00! So I thought, "Yeah, right, this must be some kind of scam" but like most of us, I was curious, so I kept reading. Anyway, it said that you send $1.00 though PayPal to each of the emails stated in the article. You then place your own email address in the bottom of the list at #6, and post the article in at least 200 news groups. (There are thousands) No catch. That was it. So after thinking it over, and talking to few people first, I thought about trying it. I figured what have I got to lose except $6.00, right? Like most of us I was a little skeptical and a little worried about the legal aspects of it. It follows the same regulations as the "mailed chain letters, which according to the U.S. Post Office (1-800-725-2161) is indeed legal! Then I invested the measly $6.00. Well GUESS WHAT!!? Within 7 days, I started getting money in my PayPal account! I was shocked! I figured it would end soon, but the money just kept coming in. In my first week, I made about $20.00. By the end second week I had made a total over $1,200.00!!! In the third week I had over $10,000.00 and it's still growing. This is now my fourth week and I have made a total of just over $36,000.00 and it's still coming in rapidly. It's Certainly worth $6.00. I have spent more than that on the lottery!! Let me tell you how this works and most importantly, why it works? Also, make sure you print a copy of this article now, so that you can get the information off of it as you need it.

$$

REQUIREMENTS: You must have a confirmed PayPal account. If you do not have a PayPal account you can go to www.paypal.com and follow the

instructions to set up a free account. In order to place the initial $6 into your account, you will have to confirm your bank account with PayPal (which may take a few days). PayPal is 100% secure and is used my millions of people world wide. Confirming a www.paypal.com account simply means (1) PayPal will first ask you to confirm the email you used to sign up your PayPal account by sending you an email with a link for you to click to that email. As soon as you click that link your email is confirmed. (2) PayPal will then make two small deposits into your bank account if you set up your PayPal account with a checking or savings bank account. Or PayPal will make two small deposits to your credit card if you set up your PayPal account with your credit card. Then after a few days (it takes up to a few days for these deposits to appear in your bank account or on your credit card statement) then after a few days you go back to the www.paypal.com website and sign in. Then you click where it says this account is not yet confirmed. A screen will pop up that gives you 2 boxes to fill in. You then enter the numbers of the 2 small deposit amounts (two separate 2 digit numbers) that were deposited to your bank account or credit card. Now you have a working and confirmed PayPal account and can receive payments.

$$

[STEP 1]
Send, though PayPal, $1.00 to each email on the below list. Make the subject of the payment "Email List" and in the comments, write "PLEASE PUT ME ON YOUR EMAIL LIST." What you are doing is creating a service by this - and best of all you are not giving your address to anyone you do not know. THIS IS ABSOLUTELY LEGAL!! YOU ARE CREATING A SERVICE. Here are the latest PayPal e-mails on the e-mail lists:

#1)brittany...@excite.com

#2) mth...@renc.igs.net

#3) Mishav...@aol.com

#4) nike31...@aol.com

#5) careent...@hotmail.com

#6) jjrvn...@hotmail.com

www.paypal.com

Subject of Payment: ***Email List***

Comments: ***PLEASE PUT ME ON YOUR EMAIL LIST***

[STEP 2]
Now take the #1) email off the list that you see above, move the other addresses up one (6 becomes 5 & 5 becomes 4, etc) the put YOUR email address (the one used in your PayPal account) as #6) on the list. **MAKE SURE THE EMAIL YOU SUPPLY IS EXACTLY AS IT APPEARS IN YOUR

PAYPAL ACCOUNT**

[STEP 3]
Change anything you need to, but try to keep this article as close to original as possible. Now, post your amended article to at least 200 newsgroups, message boards, etc. (I think there are close to 32,000 groups) All you need is 200, but remember, the more you post, the more money you make - as well as everyone else on the list! In this situation your job is to let as many people see this letter as possible. So they will make you and me reach!!!! You can even start posting the moment your email is confirmed. Payments will still appear in your PayPal account even while your bank account is being confirmed.

$$

DIRECTIONS ON HOW TO POST TO NEWSGROUPS/MESSAGE BOARDS.

[Step 1]
You do not need to re-type this entire letter to do your own posting. Simply put your CURSOR at the beginning of this letter and drag your CURSOR to the bottom of this document, and select 'copy' from the edit menu. This will copy the entire letter into your computer's temporary memory.

[Step 2]
Open a blank Notepad file and place your cursor at the top of the blank page. From the 'Edit' menu select 'Paste'. This will paste a copy of the letter into notepad so that you can add your email to the list.

[Step 3]
Save your new Notepad file as a .txt file. If you want to do your postings in different sittings, you'll always have this file to go back to.

[Step 4]
Use Netscape or Internet Explorer and try searching for various newsgroups, on-line forums, message boards, bulletin boards, chat sites, discussions, discussion groups, online communities, etc. EXAMPLE: go to any search engine like yahoo.com, google.com, altavista.com, excite.com, then search with subjects like "millionaire message board" or "money making message board" or "opportunity message board" or "money making discussions" or "business bulletin board" or "money making forum" etc. You will find thousands and thousands of message boards. Click them one by one then you will find the option to post a new message.

[Step 5]
Visit these message boards and post this article as a new message by highlighting the text of this letter and selecting 'Paste' from the 'Edit' menu. Fill in the Subject, this will be the header that everyone sees as they scroll thru the list of postings in a particular group, click the post message button. You're done with your first one! Congratulations! THAT'S IT!! All you have to do is jump to different

newsgroups and post away. After you get the hang of it, it will take about 30 seconds for each newsgroup! **REMEMBER, THE MORE NEWSGROUPS AND/OR MESSAGE BOARDS YOU POST IN, THE MORE MONEY YOU WILL MAKE!! BUT YOU HAVE TO POST A MINIMUM OF 200** That's it! You will begin receiving money within days! **JUST MAKE SURE THE EMAIL YOU SUPPLY IS EXACTLY AS IT APPEARS ON PAYPAL.**

Have fun!

>What if you are trying to tune a ground plane for the aircraft band? I
>mean, you cant transmit on this. I just want to listen.

Figure out the middle frequency of the range you are interested in,
cut your radiator & radials for that length, build it, install it,
listen with it. I wouldn't bother trying to tune it. Figuring that
traffic on VHF air is typically @ 120 - 136 MHz the end result is to
cut elements about 22 inches long. Being as you indicate you are also
interested in the 2 meter ham band you're probably about as well off
to just make it for that band and you can use it for both.

I really suggest you spend a few dollars on the ARRL Antenna book, you will find all your answers and more in that text as well as gaining a better overall understanding of antennas that will serve you well.

i just wonder does anyone know of any links to articles on a small superconducting antenna say for hf frequencies

what would happen if i build say i'd have to stay physically small , so say a 1/4wave verticle on 10m and then made that antenna supercondutive?

the antenna would technically have like no resistance that i know then i get fuzzy

wonder what happens both technically speaking and if anyone tried it, was it a 'great' antenna rx or tx wise?? any pro's con's of such a design

aside from the obv cost and impracticaliaty of pumping Lhydr/liq helium or nitrog into it etc

Source record: 83776

Assuming the terminal resistance of a resonant dipole is 72 ohms,
then a ground plane separating the halves of the dipole means the
terminal resistance of each half is 36 ohms. Thus the terminal
resistance of the half-dipole over the ground plane is also 36 ohms.
The terminal resistance of the half dipole operating against the
radials bent down can then be any value between 36 and 72 ohms,
depending on the angle of the bending. If the bending changes the
angle from 90ï¿½ to 180ï¿½ the resistance has changed from 36 to 72 ohms.
The terminal resistance will be 50 ohms at some angle in between, and
is usually close to 45ï¿½.

Hope this helps in understanding what occurs from bending the radials
downward.

In the Illinois, I see 2 primary systems.

The cross yagi - pointed skyward is for satellite reception of the data [southern sky - about 40 degree angle] for water levels of watersheds, streams and rivers. You will usually see them at dams, some bridges or confluences of streams/rivers.

The Dept of Transportation in Illinois (and many other states) have small weather stations along the tollways, interstates and major 2 lane highways for weather conditions throughout the state. They will have a small UHF yagi and it not unusual to see these small weather stations high traffic areas or bridges. Bridges allow for additional sensors to measure freezing conditions on bridges or water levels in flood prone areas (cooperatively sending data to NWS and other services).

The Army Corps of Engineers also has a number of stations for the Illinois and Mississippi River watersheds, for proper control and management of the lock and dam system above St. Louis (St. Louis, Rock Island, Omaha and St. Paul Districts).
http://www.mvr.usace.army.mil/

Many of these gauges are cooperatively managed by the Army Corps and other federal, state or municipal agencies, such as: USGS, NWS, universities.
This specific gauge is at the Hydraulics Laboratory (on the Iowa River) at the University of Iowa in Iowa City, IA

Message-ID: <10u6p7kerannc68@corp.supernews.com>
Source record: 83781

A number of superconducting antennas have been built and the results published. The ones I recall seeing were using the newer high temperature superconductors, although it can be done with conventional superconductors also.

It doesn't seem to be generally known that superconductors have zero resistance only at DC. Their resistance is finite at any frequency above zero. It increases with frequency, and it also increases as the temperature rises toward the critical temperature (at which the material ceases becoming a superconductor).

The resistivity of copper drops pretty dramatically at cryogenic temperatures, so copper becomes pretty hard to beat at RF, particularly if the temperature is getting anywhere near the critical temperature of the competing superconducting material.

The potential advantage to be gained from a lossless antenna is that a very small, efficient antenna can be made. The problems are:

1. You have a really tough matching problem, and will have severe loss in your matching network unless it's also superconducting.
2. If you do keep the antenna and matching network losses to a small value, a very small antenna will be very narrow banded.
3. You'll have to keep the temperature far below the critical temperature if you want to do much better than copper. This probably means cooling to a few degrees Kelvin, which is expensive and not compatible with putting antenna high and in the clear, let alone making one that can be rotated, for example. And the advantage of a small antenna is likely to be negated by the size of the cooling equipment.
4. Because the antenna will have finite resistance and presumably a small size, application of transmitter power will cause heating. This heat has to be removed by the refrigeration equipment to avoid raising the temperature too much.

A google search on "superconducting antenna" will bring you a lot of papers, but probably not much in the way of commercial products. While interesting in the laboratory, the above problems limit the practicality of the idea.

All the satellite weather/water data ground stations I can think of use an uplink of around 401 MHz. (There is NO downlink to these ground stations; their TX is controlled by clock controlled TX time slot.)

The government geostationary satellites, like GOES 7, are downlinking the data to a Central site in Virginia on around 4 GHZ, I think, and higher. From there, the raw data is processed and sent back out to several differnet locations, including more satellites for relay.

Good question. That method has a good reputation for portable 4-squares, as used by some MegaDXpeditions. Just roll it out, and away you go.

But it may not be so good for fixed stations, because once it's down there would be no way back. After the grass has started to grow through it, it will be impossible to rip up again. If the mesh began to rot after a few years, it would be very difficult to start again with conventional radials.

Looking further ahead, laying mesh would 'sterilize' the area for any kind of future cultivation, unless the whole top surface was planed off and dumped.

So the question is: how long will galvanized netting or mesh last in your particular soil?

It is an option I am seriously considering for the new site, but will take local advice about soil conditions.

Hi, distinguish three types of grounding:
1/ RF ground. You do not need any with a dipole and QRP. Moreover, a spike in the soil a VERY poor RF grounding. Avoid ground plane and other antennas, requiring a huge radial system as an RF ground, for temporary installations. (There is one exception: 2 - 3 radials running directly into sea water are enough if you work on an ocean beach. A vertical is a perfect DX antenna in this case.)
2/ Lightning protection. You do not need any for portable operation. If a storm approaches, pack you equipment and leave the park. It is the best lightning protection not to be there :-)
3/ Static bleeding. It is a good idea to give the static in the dipole a ground path. The spike in the ground is O.K. for this purpose.Connect the case of your TRX to it by a thick, short, stranded wire.

Galvanised conductors are really not as good as copper at RF, conductivity
is much lower. Probably not much of a problem for a 50 ohm or more antenna
but for an electrically short one, as might well be used on the lower bands,
the increase in resistance can be significant. Copper is a better choice if
the increased cost is not too significant. Tinned copper is really tin wire
at RF so it is not as good as plain copper.

The smaller the burial depth the better the ground plane will be, in general.
In fact much better results have been obtained with elevated (usually about
6 ft.) radials, but 'the powers that be' usually reject this alternative.
Disguise as a pergola or frame for training some type of plant is a possibility.

Copper will be almost permanent in most soils, galvanised iron wire may only
last a few years, so if you don't plan on repeating the installation the best
choice is plain copper, either insulated or not, with tinned copper a moderate
second and galvanised iron third by a fair way.

Any will be significantly better than mud and stones which are known to be
poor conductors at RF.

When I was in high school, my Dad had a very large wire chicken
pen. I mounted my 33' downspout vertical on top of it and used
the wire mesh for a slightly elevated ground plane. Worked All
States with it except Idaho (darn it).

OK till it rusted away. Some very fine antennas have used
metal roofs for their ground planes.

Depends on how you define "better".

For an elevated antenna, once you get beyond about 3 or 4 radials, the increamental difference in performance for added radials is such that you would never notice it in a practical application.

A solid plane has the disadvantages of being heavy, has a much larger wind loading, and is difficult to "droop" to get closer to 50 Ohms.

You can download the demo version of EZNEC from http://www.eznec.com/ and model a simple vertical with varying numbers of radials and see for yourself.

Well I would say that if mobile phones are eventually proven to be bad for your health, it is most likely to be the phone itself that is the culprit rather than the mast mounted tx at the local school etc; a point that still has not been made by the media or, it seems, anyone providing them with information.

It is probably worth noting that, in my experience, most children use their mobiles almost exclusively for 'texting' rather than 'talking'; presumably this carries significantly less risk perceived or otherwise.

I agree. Proximity is the dominant factor at work here. That's why
these scare stories about mobile phone masts and cancer are such
total nonsense.
There may well be some significant risk associated with the
conventional use of mobiles right next to the head, though. The EM
field is bound to invade brain tissue and the effects of such exposure
to even low levels of near-microwave frequencies are as yet not fully
known.

Thanks for that. Pretty useful those trees then. There are a number of large trees in the village and have to be very big to survive the winds at this altitude. Not sure how a tower would fair up here - and probably not necessary according to some coverage map simulations I've been doing - http://home.btconnect.com/g1lvn/eqso/maps/

It's the altitude, only the big ones can cope with the near constant winds up here - the little ones just get uprooted. There are at least 3 over 80ft.

Ian, theres's far too much unwarranted fuss about ground radials in ordinary English gardens and back yards. Just lay a few wires, 6 to 12 in number. beneath a trodden-on, compacted soil surface, with lengths of a few metres, perhaps 5 to 10 metres, and away you go.

Don't forget to attach to the incoming main water pipe and the domestic plumbing system if you have one. Also the electricity supply ground. And then stop! Or stop before then and see how well it works.

Reg.

>help with this problem?

Hello Glenn,

I've had some experience with the QFH, Glenn, but I don't consider
myself an authority. However, I'll try to help you with the problem,
but first I'll need to know the form you used in your model. Is it
the self phasing type, with the inductive bifilar longer than the
capacitive one? Or are both bifilars of the same length and fed with a
power splitter and a 90ï¿½ hybrid? If it is the self phasing type what
diameter is the tubing? And have you reviewed my data on the subject
that appears in Reflections?

If both the copper and stainless steel models are fabricated in
exactly the same form there shouldn't be much difference in
performance due the different materials. I don't believe the
difference in resistivities of the two materials should have a
significant effect on their performances, unless your bifilars are
made with very small diameter wire. If you used the self phasing type
the tubing diameter should be approximately 3/4", in which the
difference in resitivities would be absolutely insignificant.

So Glenn, give me the details of your QFH so that I can be of more
help.

Walt, W2DU

More sense could be derived by considering lightning and radio-ground conductors to be transmission lines. It's also more simple than reams of words.

But perhaps its asking too much of the present-day school and engineering educational system which neglects arithmetic.

Ignorant school teachers frighten pupils by calling it Mathematics. As I've said before, the culled kids who live in the sewers of Rio de Janerio, South America, are better (self) educated.

Simple. The context for the information posted is that Bean held a VHF
licence for many years before getting the HF licence. In my own case,
I have never been interested in VHF, confining myself to HF and
ground-mounted verticals, where the option of sloping any radials is
not available. I also believe that Walt's information has been
published in roughly similar form many years ago, although I don't
have the reference to hand.

Further, my original post on this also said "...an interesting
contribution, for which thanks are due to the OP...", which you
snipped.

Yes, it's a usual load of Tosh, the opening paragraph says it all, even a so called expert admits he doesn't know.

"Parents should ensure their children use mobile phones only when absolutely necessary because of the potential health risks, an expert is warning."
Then in same sentence,

"The latest study by Sir William Stewart says there is still no proof mobile phones are unsafe,"

The vision of angry villagers with flaming torches spring to mind every time I hear about objections to mobile phones/masts.

Doesn't it somewhat depend on frequency? I.e., how electrically large those radials appear to the antenna?

I ask due to having seen how commercial AM radio station antennas are built -- usually something pushing a dozen radials, often over a wire mesh as well.

I'm thinking that in the case of a commercial station, they often multiple phased antennas to try to precisely control their radiation pattern, in which case have each antenna be 'as ideal as possible' probably helps.

Mr Bean.
Airy......
I haven't got the know how or the time to build my own transceiver - and I admire anyone who has. Wonderful talent to have.
I have so far followed all the steps suggested by the RSGB - I obtained the foundation license book and studied it. I then attended a course at Poldu Amature Radio Club in Cornwall and at the end of this training I passed a basic Morse test along with a pass in the written test paper. This entitled me to a apply for a call sign as a beginner. I am now waiting for an intermediate course to begin and I will study again and hopefully pass first time. Next will be the advanced course and by then I hope to have obtained enough knowledge be called a Radio Armature.
In his welcome to me at Foundation Level Peter Kirby, GOTWW, General Manager of the RSGB said:
"Record numbers are coming into the Hobby at the foundation Level and well over a thousand of these are under the age of 21". "The continued success of the revival is in our own hands." "We must promote and encourage this wonderful hobby at all levels". If we all pull to-gather we have much to look foreword to.

So there you have it Mr Bean - So far I have found everyone I have come into contact with to be most helpful and enthusiastic.
I rather get the feeling you are against anyone who is a "beginner" which is a pity.
I don't know why you feel like this.. I respect your opinion but - not all beginners are "CBers" you know. And not all CBers are rude either.
Perhaps you considerable expertise might be put to better use in helping newcomers instead of condemning us !

Notice the words "For an elevated antenna" which presumes you are working
at a frequency where there is no problem with 1/4 wave radials.

For low frequencies, as in AM broadcast and the lower HAM bands, elevated
antennas become impractical and must be ground mounted, which means the
radials are usually buried as well as there may not be enough room
for 1/4 wave radials.

For radials on or in the ground, usually 4 to 8 1/4 wave radials is
good enough.

If space is limited so 1/4 wave radials aren't possible, the number
required goes up.

The ARRL Antenna Handbook has a good discussion on this.

You might also look at http://www.cebik.com/radio.html which has a couple
of articles about radials, buried and otherwise.

Stryped wrote:
'"How would you go about tunibg a ground plane antenna?"

Ed Laport explains how to tune a ground plane with (4) equally-spaced too-short radials. He connected one radial with its partner sharing the same alignment to make a resonant 1/2-wavelength. He determined resonance as maximum current in the loading coils. He writes on page 140 of "Radio Antenna Engineering":
"Tuning (the radial`s loading coil) is done by maximum current in the two (radial) wires using a center-connected ammeter or wavemeter near one of the (lloading) coils away from the oscillator to avoid direct pickup from the oscillator."

Lacking loading coils, one can determine maximum current at resonance in the radial wire itself.

Best regards, Richard Harrison, KB5WZI

The height of the antenna above ground in wavelengths. Yes, at a 1/2
wave
or more up, even just two radials are pretty decent. But at 1/8 wave or

lower, 2 radials are just barely above the "waste of time" level as far
as
reducing ground losses... Take two ground planes. Both are at 20 ft at
the base. Each has two radials. But one is for 145 mhz, and the other
is
for 1.85 mhz. Do they have equal ground losses? Not hardly... MK

I'm not against beginners; but beginners must begin at
the beginning; and the beginning is not the issuance
of a licence in what is a technical pursuit.

As to CBers, au contraire! - all those who come onto the bands with
M3 callsigns are indistinguishable from CBers - little if
any technical knowledge and a requirement to use rigs of
a type approved by the Britland and with limited power levels. Just like
a CB licence, you get the M3/CB Fools' Licence within 2 days
of starting out from scratch. As the RAE was tackled and then
passed by otherwise-unqualified self-taught 14-year-olds I cannot
see any reason why the standards needed to be lowered to let
a licence be given on a plate to those even less qualified than
the unqualified 14-year-olds.

Such licences are not Ham Radio licences by any stretch
of the imagination, and I regret that you have been deceived
by the commercial interests of the book publisher, the RSCB,
if you have been led to believe otherwise.

I help and encourage many beginners, but never those
of the CB persuasion in the M3 guise.

I do _NOT_ condemn you; I merely refuse to associate
with you because such association will do harm for the
long term future of Ham Radio as a technical pursuit.

Sorry, Reg, you have no way to know how many radials someone else needs.

The 'right' radial layout for any given person will depend on their available space, their resources, their limitations, their style of operating (casual, DXing or contesting), and above all their antennas - none of which you actually know.

For example, in presuming that my next radial installation will be in an "ordinary English garden", you'd actually be wrong on all three counts!

To everyone else out there: if you want to know how many radials you need, go find out everything you can about radials, from every possible source. There's lots of it out there. With each bit of information you find, judge its probable reliability and its relevance to your particular situation. Then make your own decision.

My 1978 Antenna Handbook by Orr & Cowen, page 92, references drooping
radials at a 45 degree angle for a better impedance match, raising the
gain of the ground plane antenna by about 0.5 decibel over the normal
configuration.

'Course Walt probably preceeded those guys :-)

And you never originate personal attacks?

So what is the story with the CB in the Land Rover? The off-the-shelf radios that you owned, but had to return for repair because you were too nervous? Your job at Westinghouse?

Are you going to tell the truth, for probably the first time, or will you now suffer from the usual ISP problems when challenged?

Do grow up.

You are talking a little over this sailor's head but I think I got the jist of it.

The antennas are basically Bill Sykes and Bob Cobey's design. http://www.askrlc.co.uk/. I did change the ratio of height to width a little but verified the dimensions with John Copens' calculator.

The loops are different lengths so I would say it is self phasing. Both antennas are 3/8" tube but the copper is .065" wall and the stainless is .028" wall. Also at corners I used long Ell sweat fittings on the copper tube and bent the stainless on a 3/4" radius but the total centerline lengths are within half a mm on both antennas.

I have tried two different balun designs. One is Paul Hayes design http://web.ukonline.co.uk/phqfh/phbalun1.pdf built inside a film can and the other just 4 turns of RG58U around the 1 1/2" support column. The RG58U balun worked better than the film can (probably due to my poor workmanship) but the relative performance between the two antennas was the same.

I did read your QFH article in Reflections 2. Even understood about half of it. :-)

I have plenty of stainless tube and building these things and seeing how they work is fun so starting over from scratch would not be a problem. Would 3/16 solid rod work better?

I thnk it predates 1978 by some margin. I may even be in one of the old
"Admiralty Handbooks", if anyone has a copy to hand they could check.

The explanation is a fairly standard one, although Walt does express it
well. If Walt is the originator of the idea I suspect he has a many more
turns on the coil than he is admitting ;-)

That sir is your choice.
I did not make the rules- I am only following an approved path.
I suppose when I receive the full license then it will be different will it
?
You are not giving a convincing argument are you - how can I be less
qualified than an unqualified 14year old ?
Your statements are insane. Thank goodness not all people are as foolish as
you.

The reference I had in mind was an article or item in the RSGB's
flagship journal (Radio Communication at that time?) which had a
picture of the two-radial vertical and a description of what happened
when the radials were progressively angled below the horizontal. This
must have been 15+ years ago. I can't recall now if it referenced any
of the said gentlemen's works, but the parallels are there.

I'm sure it is much older than 15 years- it was around when I did my RAE
(more than 15 years !). I'm pretty sure it is the the old Admiralty
Handbook, but I can't lay my hands on mine. You see a similar effect when
making a dipole into and inverted V.

It is certainly taught on at least one Advance RCE course ;-)

Once upon a time....I had an 18AVT trapped vertical, which due to the
lack of gardening activities in the winter, I had added a number of
insulated wire radials lying on the surface of the grass. I kept
adding to these as time went by and wire became available.

One night, after a few evenings listening to the DX on 80m, I gathered
them all into a small arc pointing at the Caribbean. There must have
been 200 or 300 radial wires spread over ~10 degrees.

A local Amateur friend using an FT200 tuned up and waited until a KV4
station called, and he was the first station pulled out of the
following European pile-up, with a cracking signal report. It's just
anecdote, but I believe the 18AVT was working well in the manner I had
anticipated. It's my belief that you can't have too much in the way of
radials.....but each to his own.

From "Radio Handbook" by Bill Orr, 20th edition, copyright 1975,
section/page 27.9: "The feedpoint impedance of a ground plane may
be raised to about 50 ohms by drooping the radials down at a 45
degree angle." Anyone got an earlier edition?

What?

;-)

I heard (no pun intended) that the YAAH committee report states that most of the talk about health being put under risk by mobile phones/mast is totally bollox.

I have to agree, before anyone spouts off about being sick due to a nearby mast perhaps the investigators ought to check the contents of moaners fridge etc first.

Is that 10 years continous use? If so, most youngsters will be death by the
time they are 18, if the 'music' hasn't 'got them by 15 ;-)

I'm glad I'm too old to like what passes for 'music' these days ;-)

I assume you mean deaf? Few people have used cell phones
for ten years already. Some of those few are starting to
get tumors inside their ears. I have switched over to a
headset for my cellphone activities after having one
for about three years.

December 2004, page 20: "Cellphones Linked To Brain Tumors"
"No tumors were associated with less than 10 years of
cellphone use." There will be about 50 million people with
10 years of cellphone use in 1907. I won't be one of them.

Indeed, thinking of something else as I typed. Its the 'music' ;-)

>Few people have used cell phones
> for ten years already.

Not sure about that. The mobile phone was an icon of the 'Yuppie' era (along
with the Filofax, BMW, Rolex, etc.) That was mid 1980s.

I'm pretty sure we one of the early 'next generation' phones (digital) in
about 1990.

>
> Have I upset the apple cart again?

Once again I proudly don the mantle of a Reg's Old Wife.

A common-mode choke, aka "choke balun" or "current balun" can have the effect Reg mentions, but that's not the only possibility. Depending on the lengths of the antenna and transmission line and the placement of the choke, it can reduce the common mode current to a much lower value everywhere on the line. This is done by the same mechanism as an insulator reduces the current induced on a guy wire -- by making a formerly resonant line non-resonant. In stubborn cases, two (or perhaps very seldom, more) chokes placed about a quarter wave apart are required to get a low value of common mode current everywhere on the line.

The general principles are easily illustrated by modeling(*). In practice, the actual path along the feedline from antenna to ground isn't well known so can't be modeled well, and some experimentation might be necessary.

(*) Anyone having an EZNEC program, including the demo, can look in the manual index under "Coaxial Cable, Modeling" for information. To simulate a choke balun, insert a resistive or inductive load in the wire which represents the outside of the coax. 500 - 1000 ohms is a reasonable value to use.

Roy Lewallen, W7EL

You're right, page 179: "Another matching trick with the ground-plane
is to droop the radials downward, adjusting their angle below the
horizontal until the antenna feed impedance becomes 52 ohms. This
usually occurs at about a 45-degree angle."

Just checked, it One2One launched in 1993, and there were other systems
before that.

Hard to believe, I don't recall a time when we weren't plagued by the
'mobile'.

I smell some faulty logic, just because "No tumors were associated with
less than 10 years of cellphone use" you can not infer that tumours
should be associated with more than ten years use. Since handheld mobile
phones have been in use for over ten years there should be statistical
evidence of tumour induction, in fact give the large proportion of the
population using such devices the stats would indicate some tumours in
less than ten years. Where are they?

Kids considered by the City Authorities to be a nuisance, living with rats in the sewers of Rio are ocasionally culled, perhaps not explicitly by the Authorities, to reduce their nunbers by police armed with guns.

Amongst other ways of making a living they survive be selling home-brewed cigarettes, loaded with cannobis and more powerful drugs on the city streets. It is not surprising why the Authorities consider them to be a nuisance - it has a bad effect on the wealthy tourist trade.

Now selling cigarettes involves monetary and arithmetical transactions. Accepting bank notes and coins and giving correct change. Mental calculations involve percent of drugs per inch of cigarette length, the number of cigarettes in the pack, wastage etc. All must be done very fast before an armed policeman appears. And must be done accurately and honestly to avoid upsetting customers with the consequent longer-term bad effect of loss in trade.

There has evolved in the sewers of Rio an arithmetical method of addition, subtraction, multiplication and division, altogether different from the Arabic procedures (Baghdad, Basrah, Mosul, before foreign weapons of mass destruction were introduced) now adopted by the rest of the educated world.

Not so very long ago a small party of professors, Phd's, students etc., from an English univerity made an expedition to Rio specifically to investigate this apparent revolution in the very foundation of Mathematics.

They returned with a new insight into how the human brain works with numbers and retired to study and then present their findings.

Since then all has been silence. I have not spent much time with Google. But there is no doubt that the self-taught sewer kids of Rio are better educated at arithmetic than the so-called engineers who argue amongst themselves in words on this newsgroup without any use of numbers and relative quantities.

Thanks. Here's what the article really said:

"Researchers at the Karolinska Institute of Environmental Medicine, in Stockholm, Sweden, have found an association between long-term cellphone use and a rare, benign tumor, causing concern among radiation specialists and epidemiologists, though they emphasize that the results haven't been replicated yet. Scientists now eagerly await results from other studies under way around the world.

Published in the November issue of the journal _Epidemiology_, the Swedish study, led by Stefan Lï¿½nn of the Karolinska Institute, looked at 148 people who had acoustic neuroma and compared them with 604 healthy people. It found that people who used cellphones for more than 10 years doubled their risk of developing the tumor, a benign condition affecting one in 100 000 people. . ."

So when you compacted this into the statement that "cell phone use for ten years results in a benign tumor that causes hearing loss", was it an emulation of today's journalistic technique, or just the effect of years spent working with binary circuits?

Looks to me like it said that a single study, yet to be replicated, of a small group of people indicated that long-term cell phone use caused a doubling of the risk of a rare benign tumor, raising the odds of getting one from about 1 in 100,000 to 1 in 50,000.

So when you compacted this into the statement that "cell phone use for ten years results in a benign tumor that causes hearing loss", was it an

emulation of today's journalistic technique, or just the effect of years spent working with binary circuits?

Firstly, you have to ask yourself what is meant by 'ten years of use'.

Does it mean

- owning one for ten tears?
- having it switched on for ten years?
- using it for x hours a day for ten years?

The meaning of 'ten years' hasn't been made clear so far, at least on
this ng.

Then you need to take into account of the mechanics of tumour
initiation and development. There are thought to be five or six events
in the initiation and growth of a tumour to the stage where it can be
clinically diagnosed. Only one of these is associated with the
causative factor, which will have its own rate of effectiveness, and
so will each of the remaining steps.

Unless the statistics have been very carefully researched and
manipulated, and they may well have been, the numbers reported should
be treated with some caution....

Google is a wonderful thing, my friend. Try "Weather fax" as a search
topic.

The cheapest approach seems to be a "sound card" weather-fax
demodulator program (runs on Windows or Linux or other Unix variants -
commercial variants around $100, many freeware variants available for
downloading), an inexpensive "PC sound-card interface to radio"
interface (RigBlaster, Buxcomm RASCAL, or any of a zillion homebrew
isolators costing perhaps $10 to build), a suitable antenna (a
homebrew yagi, or an "eggbeater" with omnidirectional overhead
coverage).

Would a ground plane work? Are these immages pretty clear?
Do you have to have ssb capability?

741. Re: "Maxwell's Equations"? (Was: Re: In a ground plane, what dictates the number and spacing of radials?)

Newsgroup: rec.radio.amateur.antenna
Date: 2005-01-11 22:26:54 UTC
From: fractenna@aol.com
Message-ID: <20050111172654.16401.00000036@mb-m16.aol.com>
Source record: 83680

Radials function as a counterpoise, and, when there are enough radials, a ground plane.

If you wish to attenuate ground losses, then it is best to make the most of the surface by using as many radials as possible. The first dozen+ are the most critical in reducing ground losses. Even a dozen or so helps substantially or over 3, for example. Several dozen reduces ground losses substantially.

Elevating radials always helps.

As I said in my response to your first query on the subject:

Google is a wonderful thing, my friend. Try "Weather fax" as a
search topic.

There's a massive amount of useful information out there on the Web.
You're going to learn faster, and more, and better, if you buckle down
and do the work of looking for it yourself, rather than continually
firing off dozens of pleas asking people to read you the Cliff Notes
version.

You in the USA already? ;-)

Already I have used an already mobile phone for well over ten years already.
(not too sure how to punctuate that in the USA vernacular) ;-)
I see no signs of ill health in either myself, or my daughter already. We
both went with Orange about the same time. (A British mobile phone network)
Now Orange work at about 1.8 Gig? At that time, that was about the highest
frequency phone system that was going. Now we have systems that work at 3
gigabyte? already. Or do they operate at even higher frequencies already?
I'm not to sure already.

Right! I'm off to bed already. ;-)

Dave

Isn't Orange an offshoot of Hutchinsion Telecom which was, I think, from
Hong Kong?

Actually Dave, Cecil's use of "already" was quite appropriate. Just
because it may not be 'our' English doesn't make it incorrect- for good or
ill US and UK English are diverging. Languages change. In fact, there is
some evidence the US English is nearer to old English than current UK usage.

Not to mention using the MP3 or Radio features with the volume too high. Or
RSI in the thumbs due to over texting.

Even worse, terminal boredom watching phone geeks comparing features. What
is wrong with a basic phone?
Some things are best simple:

Mobilephones (Proud owner of a Nokia 3310.)
Watches (I don't even like quartz watches, give me a mechanical automatic
any day.)
Razors (why do people like electric razors?)
Toothbrushes (electric toothes, I ask you).

I bet that driving a car to work every day raises the likelihood of a multiude of serious health illnesses by an order of magnitude, and those risks are a lot greater than 1 in 100,000 to begin with!

A lot people don't seem to reailze that lifestyle choices (where you live, what you eat, etc.) have a vastly greater influence on their likelihood of coming down with some dreaded disease than most forms of new technology do...

(Although I am all for continuing research so that appropriate levels for polluting gases, EM radiation emissions, etc. can be set... but of course 'the appropriate level' is at least as much if not more a political problem than a technical problem.)

I like mechnical watches, but there's something to be said for dual time
zones, chronographs, count down alarms, etc. too!

> Razors (why do people like electric razors?)

Mainly laziness; the last thing I want to do when I'm still groggy in the
morning is deal with changing a double-edged razor blade.

> Toothbrushes (electric toothes, I ask you).

I'd speculate that _most_ people do a better job of cleaning with an
electric toothbrush than with a 'manual...'

> simple, multiple element yagi?

The spacing of the elements and thei angles they're mounted out (a yagi consists of a regular old dipole with a reflector and a bunch of directors added).

> How does one measure what the impedance is or will be?

The equations for designing a Yagi are rather involved, but you certainly could use them if you're dead set on it. Otherwise, you use an antenna modeling program such as NEC to predict the impedance, and an antenna analyzer to measure the impedance of an actual antenna. (Internally, an antenna analyzer is measuring the SWR [and relative phase] of a small RF test signal applied; it can convert this back into an impedance.)

Amateur Weather
http://www.amateurweather.com/apt.htm

Dave has already pointed you in the proper direction. You can also use the word "WEFAX" for google searches.
http://www.dxradio.co.uk/wefax/

UK site - Time-Step
http://www.time-step.com/

http://www.satsignal.net/

Remember that many of these images are NOW available to you via the Internet and various web sites !

2 major types satellite are available:
Polar APT orbiting (VHF around 137 MHz)
APT satellites give about 12 good images a day, wherever you are in the world. The resolution is 4km per pixel and there are visible and infrared sensors. This is a simple system where the satellite is in low earth orbit and very easily received at 137MHz (bandwidth of 30 - 50 kHz required by receiver). The two frequencies in main use are 136.50 for NOAA 12 and 15 and 137.62MHz for NOAA 14. A simple crossed dipole antenna can be used or a Quadrifilar helix antenna (stainless steel for marine usage).
http://www.w8bya.com/Wefax-main.htm

and Geostationary Meteosat or GOES (S-Band - 1691MHz)
These are the photos you usually see on The Weather Channel or your local news.
WEFAX satellites give anything up to 400 images a day and can provide relay images of the other side of the world. The resolution varies between 2.5 and 10km. There are 3 sensors, visible, infrared and upper atmosphere water vapor. The main frequency is 1691MHz and we provide a special receiver for this purpose. This signal from a 90cm (3 foot) dish and is amplified by a low noise preamplifier mounted directly on the dish.

Yes, they will work. They are just usually larger for the same gain than
other antennas. One advantage is the same reflector can be used for several
bands.

I can't imagine how I live without then. Nice mechanical hands that move, a
nice tick, and not having to wind it up. If cars were as reliable as a
Rolex, garages would be out of business.

Don't you have those snazzy clip in dual (or even triple) bladed beasts. Do
them in the dark.

Plus, a proper wet shave lasts all day. An electric tickle about 4 hours.

> > Toothbrushes (electric toothes, I ask you).
>
> I'd speculate that _most_ people do a better job of cleaning with an

I've heard that before. However, there is also the case for 'up and down'
motion (no innuendo intended) and electric toothbrushes are rotary.

True, owning for ten years but never switching on can be no worse then
any other lump of plastic and metal. Having it switched on but not
making any calls is also of minimal risk. Using for X hours per day
might be meaningful but if X is not defined it is of little value, we
also need to know what proportion of users suffer adverse effect. If the
proportion is little different to that in non-mobile phone users then
use of mobile phones can not be considered significant.

Personally I use an electric because it doesn't take chunks out of my
face. Not that I do that often with a razor, but you can bet that the
day I have an important meeting is the one I end up looking like an
extra from a slasher horror film :-)

My electric one goes up and down. It is also a completely sealed handle,
with the battery charging done inductively, and the motion transferred
to the head magnetically. I can't believe the amount of engineering gone
into something that could be done with a stick of plastic and a few
bristles :-)
(and no, I didn't buy it - it was given to me).

> What
>is wrong with a basic phone?

Unless you need the extra features, nothing. I have a digital camera
which is much better than any in a phone, my pocket radio is better than
any phone, my handheld computer is better than any phone. My mobile
phone is smaller than any phone containing "feature" I seldom want to
carry around.

>Some things are best simple:

However not automatically so.

>Mobilephones (Proud owner of a Nokia 3310.)

Depends if you NEED more than speech.

>Watches (I don't even like quartz watches, give me a mechanical
>automatic
>any day.)

My analogue quarts is more rugged and accurate but I do have to change
the battery every three years so I do have some sympathy for a
mechanical automatic.

>Razors (why do people like electric razors?)

Perhaps they find the vibration of an electric shaver to be auto-erotic,
I prefer the closer shave obtained with a real razor.

>Toothbrushes (electric toothes, I ask you).

Depends on the type; the reciprocating rotary head are more effective
than an ordinary brush, the vibrating etc. are a waste of time.

I take an engineering approach and select equipment to be effective
rather than simply rejecting anything that is not traditional (otherwise
you would have to reject all phones and use runners).

Hmm... I don't know that we NEED much of any modern technology... but I'm certainly willing to pay for it! (And it is interesting how the Internet has gone from being 'a cool toy' to something many would argue is NEEDed for 'modern jobs' in under a decade... I wonder how long telephones took to reach the same level of 'NEED'?)

Casio has some nice 10 year (battery life) models, although they're plastic so generally the case will die years before the battery...

There are also solar powered and kinetically powered quartz (electric) watches out there...

Hi John -

Welcome to the hobby, from across the pond!

It didn't look like anyone answered your question about eham.net
(note: NOT eham.com), so try this:

http://www.eham.net/reviews/detail/4779

If you navigate around the site just a bit, you will find many
more reviews on the FT-7800R version. I assume it's very
similar, but I haven't looked up the differences.

BTW, I think you would do well to ignore posts from trolls
and flamers. There is no upside to getting into a spraying
contest with a skunk. (I have done it a few times, so I know.)

Hi Ram,

Well, you have certainly picked one of the most obscure thesis to embark upon. Everyone's done it, they all have an answer, but no one could repeat it anywhere by any rationale except maybe in one fine publication:
UNITED STATES DEPARTMENT OF AGRICULTURE
Rural Electrification Administration
REA BULLETIN 1751F-802
SUBJECT: Electrical Protection Grounding Fundamentals

It does not characterize soil, but it does a very compelling job of characterizing technique, which is very valuable.

I don't know what the soil is like there in Malaysia, but you can bet that it contains all the variables that will make analysis quite a challenge. I would presume that you at least have less differences in water content and temperature than here in North America (this drives a huge difference in earth resistance).

People with less than 10 years of cellphone use suffered the same
rate of tumors as non-cellphone users. People with more than 10 years
of cellphone use suffered twice as many tumors as non-cellphone users
and tumors among cellphone users was four times more likely to occur
on the side of the head normally used for the cellphone. Where's the
faulty logic?

That was the gist of what I got out of reading the article the
title and header of which is:

"CELLPHONES LINKED TO BRAIN TUMORS, THE GOOD NEWS IS THEY'RE
BENIGN; THE BAD NEWS IS THAT THEY'RE THERE."

Your gist may vary. I assume one argument from the "no energy
in RF waves" guys will be "no energy = no tumor".

More on the subject from:
http://www.timesonline.co.uk/article/0,,2-1436543,00.html

"CHILDREN under the age of eight should not use mobile phones, parents were advised last night after an authoritative report linked heavy use to ear and brain tumours and concluded that the risks had been underestimated by most scientists.

Professor Sir William Stewart, chairman of the National Radiological Protection Board (NRPB), said that evidence of potentially harmful effects had become more persuasive over the past five years.

The news prompted calls for phones to carry health warnings and panic in parts of the industry. One British manufacturer immediately suspended a model aimed at four to eight-year-olds.

The number of mobiles in Britain has doubled to 50 million since the first government-sponsored report in 2000. The number of children aged between five and nine using mobiles has increased fivefold in the same period.

In his report, Mobile Phones and Health, Sir William said that four studies have caused concern. One ten-year study in Sweden suggests that heavy mobile users are more prone to non-malignant tumours in the ear and brain while a Dutch study had suggested changes in cognitive function. A German study has hinted at an increase in cancer around base stations, while a project supported by the EU had shown evidence of cell damage from fields typical of those of mobile phones."

The faulty logic was in the presumption that ten years use was different when your statement in Message-ID: <41e43ad6$1_1@127.0.0.1> of 'December 2004, page 20: "Cellphones Linked To Brain Tumors" "No tumors were associated with less than 10 years of cellphone use." There will be about 50 million people with 10 years of cellphone use in 1907. I won't be one of them' which made no mention of effects either use for more than ten years or non-use. I do not expect anything a simplistic as a step function at the ten year threshold, perhaps this like your previous post is also omitting essential information?

Unlike heavy mobile phone use it has been proven that increasing Oxydisation of cell structures causes, cancer, aging and ultimately death. Doesn't stop anyone breathing though does it? If we al stopped breathing there would be no cancer, no aging.

Seriously though, as an illustration, say that in 20 years time we find that the heating effect of RF from mobile phones provides a catalyst for increased oxydisation in the brain when combined with the inhilation of plastics vapour from the material used in cellphone keypd membranes to cause cancer of the nose (it could happen!!). This would be a totally unforseen risk to our health. What this report says that is as a precaution to unforseen health risks it is better not to let childern use mobile phones and audults only when absolutly necessary and to limit use. This is an example of the "precautionary principle", specifically used to limit or halt future crisis.

A lot of work it seems (at least in working out how to use the software initially), particularly as several applications appear to be used in a modular fashion, I'll have to take a look at it in more depth in a few days time.

I do something similar to this when producing MeteorSat-8 Imagery from HRIT Data.

Although meant humorously, it should be noted that oxidation is a process that doesn't necessarily involve oxygen at all!

Oxidation is the process of losing one or more electrons by an atom (which may form part of a molecule) - the species that gained the appropriate electrons is said to be 'reduced'. Redox reactions are a basic part of chemistry.

The real oxidation damage to human cells comes from the action of 'free radicals' - molecules that have gained a lone electron. These electrons are highly reactive, and the transfer of this electron to a molecule in a cell can cause (chemical) damage. If this happens to be part of the cell's DNA, then the 'message' encoded by the DNA has been altered.....which can lead to uncontrolled cell growth and reproduction, and hence The Big Casino.

Where do free radicals come from? Currently they are though to arise through pollution, fried foods, alcohol, sunlight, solvents, ionising radiation, the sources are many and varied. What can you do to prevent free-radical attack? Avoid free-radical producers, and ensure you take enough anti-oxidants through dietary supplementation....

The interested reader is encouraged to find out more through, e.g. web searches. There's a lot of info out there.

I've laboured this a bit because there are people on this ng whose level of understanding is such that they believe things like 'dehumidifiers absorb heat.....you can use this to warm up your shed'.

Hi Dick,

Yes, at the time, I was aware of the mis-spelling. But I could't think of the name 'hemp' which even I CAN spell correctly. Very interesting, its the only defect you could find in my story.

Your "If you are expected to be taken seriously" is an indication that you think there is something serious in what I say.

Regardless of South American un-culled sewer rats - Engineers who regularly demonstrate they are afraid of using numbers can hardly be considered to be well educated. (Refer to Kelvin).

This criticism is not so much directed against individuals as it is against the present-day, Western World engineering educational system in which university professors just sit on their fat, lazy, well-paid, self-satisfied arses, obtaining easy money under mutually-plagiarising false pretences.

I didn't say there was a step function at the ten year threshold
and I'm certainly not going to type in the entire article. It is
much more likely that it is a ramp function roughly emerging from
the average after around ten years of use.

A "ground plane" antenna is designed to 'fool" the antenna into thinking the horizontal radials are actually the surface of the earth. This term actually has nothing to do with grounding the antenna. However, the antenna will work better if the mast of it is grounded, since this gives the radials an actual earth ground reference electrically, and it therefore will work more closely to it's design specs.

Any antenna will be either "inductive" or "capacitive", depending on its length as relative to the frequency its designed for. If it is short for the frequency, it is usually capacitive, and if it is long for the frequency, it will exhibit inductive qualities. The combination of these inductive and capacitive factors, added vectorially, results in the "Z", or impedance , of the antenna. Impedance is actually sort of a lossless form of resistance. More info on these factors can be found in the arrl antenna handbook, available from the arrl headquarters in Newington, Connecticut.

"Z" was a factor in these discuassions and arguments I have been having with people about how their antenna's active element was "grounded' over the years. for DC purposes, it may be grounded, but they fail to take into account that the antenna's impedance to ground is actually higher than that when RF energy is applied to it... The antenna is usually "grounded", so to speak, through a reactive element that produces quite a high impedance between ground and the active antenna element at RF. If it didn't , the antenna would send and receive nothing, since all signals WOULD get shorted to ground ! But, it seems the gist of this argument, which any novice ham operator is more than familiar with, escapes them....

Of course Mr. Clark, as usual, is "right on the money" in saying that 1db is nothing. To get a 1 unit s-meter difference on the average receiver, it actually takes 6 decibels more signal, or 4 times the power, from the transmitter, to produce that signal increase.

Double the transmitter power (3 db) , and you get a half an s-unit increase.

In many cases, it is more advantageous to raise the antenna 10 feet or more, than it is to increase transmitter power, and it will often result in much more signal in the receiver, since it gets the transmitter antenna "up in the clear", where losses to the ground and surrounding obstructions drop off..

Why would RF currents flowing in the mast make the
antenna work better? Wouldn't that be about the
same as common-mode transmission line currents?

Simply put, the feedpoint impedance of an antenna is the ratio of
the total voltage to the total current at the feedpoint. In a
standing-wave antenna, like a center-fed dipole, the total voltage
is the vector sum of the forward voltage and reflected voltage.
The total current is the vector sum of the forward current and
the reflected current. The reflected current undergoes a 180 deg
phase shift at the tips of the dipole but the reflected voltage
does not. For a resonant 1/2WL center-fed dipole, the feedpoint
impedance is:

Zfp = (|Vfor|-|Vref|)/(|Ifor|+|Iref|) = low

i.e. Vfor is 180 degrees out of phase with Vref and Ifor is
in phase with Iref.

For a (resonant) one-wavelength center-fed dipole, the feedpoint
impedance is:

Zfp = (|Vfor|+|Vref|)/(|Ifor|-|Iref|) = high

i.e. Vfor is in phase with Vref and Ifor is 180 degrees out
of phase with Iref.

Reminds me of an article in QST in the '50's titled
"One dB Doesn't Matter" or something like that. This
ham had one dB loss due to an old final tube, one dB
loss due to a dirty tank coil, one dB loss in the low-
pass filter, one dB loss in a bad solder joint, one dB
loss in the tuner, one dB loss in the transmission line,
and one dB loss in the antenna. He wondered why he
wasn't getting out very well. :-)

Well, Chip, as the inventor (Dr. George H. Brown) said, two radials
are sufficient for a ground plane, but the RCA sales dept thought they
would sell better with four. But a ground plane antenna suffers no
ground losses, so using as many as possible only applies to radials on
or in the ground.

A ground plane or a tuned counterpoise does not. A rule of thumb is that if the conventional aperture is 1/2 wave across or more, you won't need the choke. Smaller and you will.

Any antenna feed with a coax transmission line will benifit from using
a choke/balun at the antenna feed point. It is just good engineering
practice to do so. It won't hurt and only can help.

No he didn't. 7dB, about one S-unit, is not enough to come to anybody's attention.

It's less than the difference between a G5RV plus coax, specially a 1/2-size G5RV, and an ordinary dipole fed with open-wire line which most people never seem to notice.

Once again, I find this fact hard to understand, when the world's fastest
growing technology, with the worlds largest budget etc can't up-grade the
language it speaks, to what the rest of the English speaking world use.

I would argue over the simplification that below 1 db is "nothing."
If one cleans up his system then it is possible that those items
that lose less than a db could add up to something "meaningfull".
But DXrs say a little db is a lot and usually they are not casual operators.
A single increase in gain of a db of an antenna can infact supply more gain
at a lower
TOA where it enables the operator to make a contact where others fail!
On my antenna I am able to drive down the TOA by more than 3 degrees
where for comparison purposes it may only have the gain oif a normal four
element
yagi that has a TOA of 14 degrees. So I consider the statement that 1db is
insignificant
a bit over the top when one is working with antennas and what one can
achieve what others can't.
Regards
Art

Of course a proportional function is more likely although perhaps not
linear however your statements that "No tumors were associated with less
than 10 years of cellphone use" and "People with more than 10 years of
cellphone use suffered twice as many tumors as non-cellphone users"
describes a step function at ten years {t = 1 for y < 10 and t = 2 for y
> 10, where y is the number of years and t the base rate for brain
tumours in a non-mobile phone using control group). Given this
simplistic step function I must have doubts about the accuracy of the
study that lead to such a conclusion

I do not expect you to type in the entire article, but you only stated
"No tumors were associated with less than 10 years of cellphone use"
which provide no information about any association after ten years.

Stryped wrote:
"I know in a ground plane the angle of the radials can, but what about a simple multiple element yagi?"

The feedpoint impedance of a resonant 1/2-wave dipole is about 67 ohms resistive (page 120 of Kraus` 3rd edition of "Antennas"). The impedance of a 1/4-wave antenna perpendicular to ground is about half the dipole`s impedance (page 568 Kraus` 3rd edition).

Drooping radials place a ground plane in a transition between a 1/4-wave perpendicular to ground and a 1/2-wave antenna. Impedance follows suit, ranging from 30 ohms with no droop to 60+ ohms with complete droop. In between, a match for 50-ohm coax can probably be foind.

An antenna element alone in free-space has a particular self-impedance. Aide by side elements are coupled. Current flowing in one ekement induces voltage in other elements nearby. This affects the feedpoint impedance of the driven element because it is feeding an array. Another name for coupling is mutual impedance. It is measured as the voltage produced in one element bivided by current in the driven element. It`s reciprocal. Either element can be driven and the other can be parasitic. The mutual impedance is the same either way. The feedpoint impedance is a complex sum of all the array impedances.. It is often tedious to calculate. Kraus shows the mutual impedance story on page 452 of his 3rd edition of "Antennas".

Cecil, W5DXP gave a good explanation of impedabce in a standing wave antenna. He showed how a high impedance at the open-circuit end of the antenna is converted to a low voltage and a high current 1/4-wave back at the feedpoint. Their quotient is the low self-impedance at the feedpoint.

Best regards, Richard Harrison, KB5WZI

I'd be very interested in seeing the basis for that statement. Or are you simply and mistakenly assuming that the ficticious 6 dB "S-Unit" so fondly and inexplicably used by amateurs actually represents a division on a typical receiver S meter? Have you checked your receiver's S meter?

Your basic ignorance of statistical data is showing. What if, starting
at ten years of use, 1% of cell phone users suffered 1% more tumors
than non-cellphone users and a year later, 2% of cellphone users
suffered 2% more tumors than non-cellphone users, and a year later 3%
of cellphone users suffered 3% more tumors than non-cellphone users
... That is certainly ***NOT*** a step function, to which you objected,
but a ramp function that is certainly something to be concerned about.
Hint: I'm surprised that you don't know that nothing changes
instantaneously in reality, i.e. a 'step function' is purely an
invention of the human mind.

Please rethink your position. If no RF current flows in the mast, a
fiberglas mast is just as good as a metal mast. If you are depending
upon the mast to furnish a ground, RF current *must* be flowing in the
mast. Otherwise, how do you know it is providing a ground? You simply
cannot have it both ways. I hope that soaks in.

Hi all,

This "over the top" and other straining to get a "louder" signal begs
a real number - like 1dB. Such testimonials (negative or positive)
are emotional comparisons.

This "over the top" expression speaks for itself. If a 12% drop is
outrageously "over the top," then there would be runs on the bank for
the 30% fall of the dollar's value in the world market. Back when we
had double-digit inflation (hmmmm, 12% is double-digit) the party now
in charge went ballistic about the state of the economy. Now that we
have outsourced inflation - 30% is cool. Merely a matter of who's ox
is being gored.

Well, so much for fun with numbers; let's look at "louder" signals.

What does it mean to be "louder" with a modern (post Depression era)
receiver? Is 1 dB perceived as being "louder?" Well, by definition:
just barely (IFF you turn up the volume control). Why do I
parenthetically add this constraint of a necessary active
participation of turning up the volume control? Because in a modern
receiver, the circuitry deliberately compensates for that 1dB boost by
depressing the gain by the same amount. Net result? Voila! 0dB by
perception and design. Well, by aural perception that is. So much
for "louder."

You "might" see (another perception) the S-Meter shift by something
less than one needle's width if that makes you feel that something has
been accomplished - in this case they could as easily calibrate the
meter in ego-Satisfaction units. Then again, maybe you would have
missed 1dB entirely (should we insist on a negative multipliers for
that ego reading?). The correct appeal is found in S+N/N where the
improvement adds clarity - merely bombasting about "loudness" is
provincial.

The driven element is a dipole and you use a seperate dipole for each band.
The spacing of the dipole from the reflector depends on frequency .

If, as you state, it went from nothing below ten years to two times
after then there was a step, it is that I object to; perhaps you do not
understand that it is a step {t = 1 for y < 10 and t = 2 for y 10,
where y is the number of years and t the base rate for brain tumours in
a non-mobile phone using control group)

Hint: YOU quoted a single value for less than ten years and single value
for above, maybe you do not understand that is a step, do I have to draw
a graph of your statement.

t

2 ----------------------

1 ---------------------------
1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17 y

Can you see what happened? Of course I object to the function you quoted
as being improbable.

Your example of a proportional relationship is not justified from your quotes, is irrelevant, and being a deception has no place in a discussion of this nature.

A 1 dB change in loudness is about the smallest level of change which is fairly easily perceived by the human ear. BUT ONLY WITH AN INSTANTANEOUS, X versus Y, CHANGE IN LOUDNESS.

To attempt to judge the difference, with a precision of 1 S-unit, between the loudnesses of a G5RV and a 1/2-wave dipole fed by an open-wire line, with a time lag of months, a change in the number of sunspots, on different bands, with a different receiver, is futility in the extreme.

Yet some people appear to have no difficulty in making the comparison.

|Hi all,
|
|This "over the top" and other straining to get a "louder" signal begs
|a real number - like 1dB. Such testimonials (negative or positive)
|are emotional comparisons.

One of the biggest thrills I've had in my amateur radio career was
pressing the key and 2.5 seconds later hearing my signal returning
from the moon. I will confess, this was an emotional response [g].
One dB does make a difference. One dB difference in transmission line
loss or antenna gain makes a hell of a difference.

I also got emotional when VU4RBI barely came up out of the noise and I
worked her a few days before the great flood or last night when 3G0YM
gave me a 59 report on 20M and not being able to tell him he was S0, I
fibbed and gave him a 53.

|==========================
|Hi Dick,
|
|Yes, at the time, I was aware of the mis-spelling. But I could't think of
|the name 'hemp' which even I CAN spell correctly. Very interesting, its the
|only defect you could find in my story.

If you would have just typed "cannobis" in Google, it would have
asked: "Do you mean: cannabis?"

|
|Your "If you are expected to be taken seriously" is an indication that you
|think there is something serious in what I say.

Never.
|
|Regardless of South American un-culled sewer rats - Engineers who regularly
|demonstrate they are afraid of using numbers can hardly be considered to be
|well educated. (Refer to Kelvin).

Hmmm. The USA is now being overrun with denizens of the countries to
the south, including no doubt some South American sewer rats. By your
estimation, the education level here should have improved.

I think not. For example, I left a pair of slacks at the dry cleaners
a few days ago. The fee was $1.75 (USD). I gave the girl $10.00 and
she broke out a calculator to determine that my change was $8.25.

Contrast this to a tale related to me by an old friend. Jim was in
the U.S. Marine Corps when the flight of the Enola Gay took place.
Shortly after, he and his group were sent up some river in China to
ferret out some Japs...sorry...Asians who hadn't gotten the word yet
that they had lost. The Marines set up a camp and immediately began a
trade relationship with the local Chinese "service industry."

Jim said it took all of 15-20 minutes for the natives to master the U.S. currency system. (It probably would have taken them a couple of hours to figure out the British system of the day [G])

back on topic,..

i still ponder if i put power into a superconducting antenna if their
is no resistance, and a given about of power would therefore 'stay' in
the antanna longer ie no resistance and a sorta flywheel effect exists
the fields would have to exist longer for fixed-given power , ..

seems that all adds up to more than a trival gain

looks like ill have to use some cheep material like copper or something
elese i can make superconduct unless i can use a supension of
conductive materials into a coolent itself an make a tube that will
radiate while being superconductive just cause i wonder if that will
work as good as a stp based liquid antenna

who knows maybe i'll stumble over 3xtra db

will the antenna stay resonant as it nears criticaltemp? and reaches it?

This discussion kinda reminds me of a tome I read (and once actually thought possible), from a CQ article by one "Dr. Shorza Gitchigoomie" (if i spelled that right), progonosticating on the magnicifiant effects of negative resistance! Like applying it to light bulbs (they absorb light)! Or, to electric heaters (air conditioning).
If this indeed would work, then why not - the lower the power- the higher signal strength! 'Corse this article was published , in APRIL, about 40 some years ago, and in the intervening years have discovered that there are some serious flaws in his research!
And I dont expect too much out of Super Conductor Antennas (if they could work well, would not they be in use at the international space station, as that temperature must be at least colder than liquid nitrogen)? or have the laws of Newtonian Physics been repealed?
I await the dawning of the new age! :) Jim NN7K

Not really, no, at least not in the commoner cases.

Let's assume that you could find a superconductor which would be truly superconducting even at RF frequencies (which today's superconductors are not, I gather). So, you could cut the loss resistance of the antenna to precisely zero, in this hypothetical case.

According to a note Reg posted some time ago, "At 3.75 MHz the resistance of 20 awg copper wire is 0.206 ohms per metre. Overall end-to-end dipole resistance 8.24 ohms."

Using the hypothetical perfect superconductor (which may be impossible) you might reduce this dipole resistance to zero. Great reduction in loss, right?

Less than you'd think. Remember, the loss resistance of 8.24 ohms appears in series with the antenna's radiation resistance (which is due to the RF energy being radiated) which will be around 70 ohms for an antenna in free space. With the loss resistance present, just under 90% of the energy is radiated ("dissipated" in the "radiation resistance"), and 10% turns into heat in the loss resistance.

Getting rid of the loss resistance entirely will thus increase your radiated power by only about 10% - a small fraction of one dB.

I would like to put a different spin on the 7dB statement below.

Where the extra gain or power really comes into play is very weak signal DXing - not the pileups necessarily.

Cases in point - my Dxing log has several contacts where using a linear got my signal far enough above the noise level for the DX station to understand me. True on phone or CW. In most of these cases, the DX was calling QRZ and no one was answering -- the DX station was so weak -- seems folks just gave up or maybe everyone worked them. Turning on the linear got me the contacts. Definitely Without Question - Worked an R1MV Malyj Vysotskij, HK0 Malpelo Is, VK9/M Mellish Reef, and VP8/G So Georgia by turning on the linear feeding a vertical multibander.

I had this happen enough times to realize this to be the real benefit of adding a linear. And it sure can't hurt in a pileup either, if you know how to work a pileup.

Using copper, the reflected current back at the feedpoint of a 1/2WL
standing-wave antenna is in the ballpark of 90% of the forward current.
Exactly how much improvement is possible?

The fact that superconductors have zero resistance above DC isn't a limitation of today's technology (although technology limitations cause current high-temperature superconductors to have resistivity greater than theoretically possible), but a fundamental property of the nature of superconductors.

What I'm saying is that a "truly superconducting", "hypothetical perfect" superconductor has finite resistance at any frequeny above DC. Imagining a material that has zero resistivity at frequencies above DC requires imagining something other than a superconductor.

It was you who described a step function and I am disputing it precisely
because it can not be as you describe, why don't you admit that your
description is wrong instead of pretending that you are not, or are you
to stupid to understand that you are wrong.

well seems everyone is 'strictly' (narrow) focused on the antenna's
resistence loss, i mentined it as the starting point as that is first
thing i think of when it goes critical... however one the resistance
drops, other effects take place no? both in the material and in respect
to other forces aside from just resistance, once it reaches near 0 and
begins being a superconductor

guess i won't know until i build it and mesure it i wanted to try 10m
really but 2m might be easier to keep chilly(0) and i am looking
foward to rig it i've got most of the stuff i think i need so far

i'd also like to build a superconductie ocilator, i'd suspect that i
could power it using a truly small ammount of power?

857. ATU capacitors?

Newsgroup: rec.radio.amateur.antenna

I wonder if there is any mileage to be had from adapting
the numerous junk-mail CD's as the vanes of ATU
capacitors?

1. We already have a form that is circular (no waste) and
with an accurately-positioned central hole.

2. There is a metallic film sandwiched between the plastic.

3. Is this film to thin to stand up to the RF currents that
will spread out across it when charging & discharging?

4. How would we make metallic contact to the film without
destroying the film at the point of contact?

5. Does anybody know the type of metal making up the film, i.e.,
can we solder to it?

6. Is the plastic of a suitable quality? Will it arc-through?

858. Setting up slitting saw for round stock?

Newsgroup: rec.radio.amateur.antenna

Is there a "kink" for setting up a slitting saw to saw through
round bar stock along the axis, so that the slot is exactly
across a diameter? (I presume this to be a similar problem to
setting up accurately for cross-drilling)

This is actually a Ham Radio application; I wish to make
up some very large banana-type plugs from the 1/4" round
bar stock that I have in small quantities. For this, I will need
to saw two diameters in a cross shape, and then splay
out the leaves slightly to make a springy and rubbing contact.

I put the saw mandrel in a lathe chuck and made a block with a hole and setscrew to mount on the cross-slide. Did this to slit the threaded end of a bolt - it has a countersunk hole lengthways through it and when a smaller screw is thightened it locks the threads. This bolt is the mount for a ball-turning attachment; I wanted to be able to lock the mounting bolt at the right clearance without having it cock or move sideways, so a locknut and a setscrew were both out.

I had to thread the hole through my block, but you don't need that. If you wanted to get fancy you could make a shouldered sleeve with your setscrew holding the stock, drill a hole in the shoulder, and two holes in the block for a pin to set your 90 degree cuts.

I make mine into Christmas decorations.
Stick in pairs using double sided foam pads, on monofilament fishing line.
Dangle a lot of these strings inside a window.

A little Googling would soon show you whether the critical factor,
which you doubtless have already determined from your preliminary
calculations is the loss tangent for the CD substrate, may well render
such a use as inadvisable.

Hi,

I'm also on dialup also.

To speed up things, just turn off load images in your browser as a
temporary
measure and that will speed up your internet browsing !
No reason to download all the images or graphis unless you want them.
Bookmark the sites you like and then turn on load images again.

Is there a library either public or university near you ?
Many have public internet computers available at no cost, just ned
a library card and perhaps a quick instrution session before they let
you online !

Regards,

wefax_dude

Hi Airy, couldn't you just use a grinding/cutting wheel to do this job?
Doesn't sound like you need any fancy jig to cut a slot or two into round
stock.

Jack

I'd put the bar in a vise and do it by hand, so what if you waste an inch of stock at a time if you aren't happy with it? This isn't rocket-science making a plug Airy, just have at it for Pete's sake. I could hold a tiny Dremel-tool or a big 1/2" drive side-grinder steady enough to do what you're asking with one eye closed.

Sorry, but there is a parallel here with cross-drilling
of round stock. You only need to be a few thou out
for it to be very apparent that the hole is off-centre.

In trying to make a 4-leaf banana plug, with the additional
consideration that material is cut away by the saw or grinding wheel, I
expect that a few thou deviation would result in some leaves
of the plug being considerably weaker. In any case, there is
a certain degree of pride in setting out and achieving a
quality result if that result can be obtained with a few
moments of extra planning.

In any case, it is not the steadiness of hand that is the issue,
but the centring of the tool over the product.

Assuming you are using a vertical mill so that the slitting saw is
horizontal, and the work is fixtured horizontal (vee block perhaps):

a/ Measure height of top of stock with vernier height guage, subtract
half the stock thickness, and add half the slitting saw thickness -
set the height guage to the resultant figure.

b/ Adjust quill of mill so top of slitting saw just touches the height
guage and lock the quill.

You now have the slitting saw bang on centre of the work.

Sorry, until you choose to tell the truth, I have
nothing further to say. What I described was a
ramp function starting at 10 years of use. It was
you, not I, who introduced the *step* function
concept.

It's certainly more economical to increase the
transmitter's power output than to supercool a
dipole.

This trick assumes you have the slitting saw in a vertical mill, the bar is horizontal, and the slitting saw teeth are straight (i.e.. not staggered like a wood saw blade).
Adjust the position of the bar and saw so that, by eye, the blade is just about touching the fattest part of the bar. Interpose a vertical 6" steel rule between the bar and the saw and move the table to very gently pinch the rule. Unless you were lucky and set the saw exactly on the fattest part, the rule will no longer be vertical. Adjust the hight of the saw until the rule is truly vertical - you will be amazed at how accurately the blade is then at centre hight.

Someone suggested this over the last few days.

As I'm having trouble with soil sticking to the spade
and creating a hole when the spade is pulled up
instead of just a slit, could someone redescribe the
meat cleaver technique?

Now, that's interesting, because it is a variation of the technique
for setting up for cross drilling (except that then the ruler is in
see-saw mode)

I have to make up about 14 such plugs.

(Although a nagging voice inside suggests that I should
also consider the "Binding Post" approach together with
spade terminals)

Damn! I knew I should have purchased that digital
height gauge at the club sale, especially as it was only
£10!

The only difficulty otherwise with what you suggest is
the tendency of slitting saws to bend under the slightest
lateral force, but thanks anyway.

Superficially the idea has some merit but you would have to machine the discs anyway (they are totally symetrical and thus the area overlapping with the fixed vanes wouldn't change). By the time you've machined then to be asysmetric, might as well have made metal plates and avoid all the other problems as well.

To problems in making variable Cs, the use of a CDROMs offers little.

Etching plates on PCB and using the fibre glass for the mechanical side is maybe a better idea.

FYI, I found an alternative tool -- it's a 12-inch blade that is
foot-operated. See the picture at:

http://www.hound-dog.com/steppin_edger.htm

Officially, it's a lawn edger, but it will also cut a slit in the
lawn. If I bury it too deeply in wet soil, the dirt sticks to the
blade, but if I'm careful, and do it in reasonably dry soil, it works
nicely.

I wonder what the background to you idea is?

New approaches to existing designs should offer one or more of:

Cost savings (cheaper materials, less man hours, ease of manufacture etc)
Better reliability and/or life (not the same thing by the way)
Extra functionality

For most things, the cost of materials is not a cost driver- the cost of the material in a variable capacitor is dwarfed by the labour and machining costs.

So, how does using duct tape help?

The CD idea falls flat as, while they may be cheap, the amount of machining 'saved' is mininmal. I suppose if you are totally strapped for cash, out of work and with time on your hands, they may offer some advantage, but you end up with a 'product' of inferior quality. Engineers who are driven by such a penny pinching approach usually end up bankrupting their company as their products are poor.

The simplest way I know to locate a line on top of round stock is this:
(BTW, you don't have to switch from vertical to horizontal modes to make it
work.)

Mount the stock parallel to the mill table, and dead-level, with the
"working end" solidly in your mill vise, and enough overhang for the
slitting saw to clear the vise when you're working on the _side_ of the rod.

True up the work with your longitudinal travel, so it's _pretty_ good. A
thou. is OK, you don't need it to tenths.

With any-ol' side-cutting bit, slowly close in on the side of the work until
the bit just kisses the metal. Then make a longitudinal cut for however far
you want the slit to go.

You've now marked a line and flat that is parallel to the axis of the rod,
and perfectly centered on the horizontal diameter of the rod.

Without removing the work from the vise, you can switch to your slitting
saw, and true up the saw to the line you've just marked -- then cut.

LLoyd

An alternative, if you know someone with a Partner cutter, or a 9" angle grinder, is to just zip along the ground with an old diamond blade, giving you nice neat slits to drop the wire into. Water it, stamp it back down, and the XYL need never know!

You don't seem to have the qualities that makes
for a _REAL_ Radio Ham, OM!

There are no labour costs when you do things for yourself!

There are no machining costs in cutting up a CD with a pair of scissors.

On what basis do you claim that a variable capacitor fashioned
from junk-mail CD ROMs is a "'product' of inferior quality"?

From the power handling capability?

From the flash-over voltage?

From the max and min capacitance?

Which companies do you say have been bankrupted by looking for
economical means of production? (Not all of us can boasts that we
are employed by profligate defence companies and are proud to
have been involved in the development of the weapons that
were responsible for the deaths of so many innocent children
in Iraq, OM)

Or is your posting below yet another example of bullshitting,
of side-stepping and of downright lying?

Doesn't need to be "exactly" because it's the diameter that is more critical
than the position of the slot - I suspect even as much as just less than the
thickness of the slitting saw off centre would not be a problem.

I made a connector (female as opposed to your male) for an old radio by
slitting brass tube. Hacksaw and vice produced good enough accuracy for an
excellent operational performance.

How about making a square fixture to hold the round part with two slits
to guide the saw blade?

I have found that a good fret/jewelers saw very handy for cutting small
items. I find it very difficult to cut 1/8 drill rod with a hacksaw
but easy with a fret saw. They cut faster than you expect.

Dude

I've been trying to build a collapsible antenna for WXSAT use. I
recognize that there is little interest in this antenna amongst the WXSAT
image group. I'm no longer active in HAM radio and have no connections
with any 'tinker/builders' around the Los Angeles area. I'm curious to know
if you have interest in communicating with me concerning your experiences
with 137 MHz satellite imaging.

Jerry

Lay the round bar stock in a Vee and put it under the saw so the saw just
touches the highest part of the rod. As long as the stock is round you'll
have a tangent to the diameter and all you need to do is start slotting,
half in two.
There used to be lots of banana plugs for sale on eBay and hamfest, quicker,
easier, and cheaper than DIY.

Come on now help yourself a little bit -- the URL you gave has the answer when you click on "Features"

It sez

Your radio shack discone antenna receives VHF and UHF frequencies between 25 MHz and 1300 MHz
(1.3 GHz), and transmits effectively at 50, 144, 220, 440, 900, and 1296 MHz. It handles a maximum transmitting output power of 200 watts and provides a standing wave ratio (SWR) efficiency of 1.5:1 or better over the receiving/transmitting spectrum.

Now why can I find that and not you ???

Are you putting us on here ????

The reason for the multiple posts is that it's the only way he can
top-post responses to individual points made in the previous post. I
think his record is about 10 replies to one post. And still he thinks
top-posting is the way to go.

The information as posted on the Web site is only part of the answer.
Heck, a good high-wattage dummy load would have a better bandwidth and
SWR than the discone, and yet it'd make a (somewhat) worse antenna.

As to the original question, is a discone "any good for both transmit
and receive?". I'd say the answer is "Yes, they're 'any good' but
they are not 'very good'."

They're compromise antennas - fairly wide bandwidth, acceptable SWR,
but a radiation pattern aimed at the sky or the ground (depending on
how you mount them) rather than out at the horizon. They're a decent
choice if you can only mount a single antenna, need to operate over a
wide range of frequencies, and don't need to be concerned about
weak-signal operations. My city ARES/RACES group uses them for
pre-sited emergency antennas at the city fire stations, community
centers, schools, and other such locations... plug an HT onto the end
of the drop cable and you're on the air. The results are quite
acceptable for working nearby repeaters, simplex to the city EOC,
and so forth.

They're a mediocre choice for serious single- or multi-band operation,
though.

Again, It's more than obvious that I said absolutely nothing
about any "step" function. That you believe a tumor can appear
instantaneously as a step function is a mental problem for
which you probably should seek professional help.

In an earlier post
http://groups-beta.google.com/group/rec.radio.amateur.antenna/browse_frm/thread/540469fb25ccbc17
I asked if anyone could identify this antenna
http://home.comcast.net/~ross_anderson/TelevisionAntenna.htm .
Mike, NZ4K, suggested I look at this site
http://www.starkelectronic.com/wing4.htm .
A close match is the Winegard CA-8098.
This is a fascinating antenna (the VHF part), consisting of two booms coming together in a V, with the elements attached to the boom off center, and the elements on the upper boom placed asymmetrically with respect to the elements on the lower boom.
Now my question is: Has anyone seen this type of antenna written up in any journal, conference proceedings, book, patent, web page, or message board; or is anyone willing to share their thoughts or unpublished work on this type of antenna?
Thanks, Ross W1HBQ

That does not tell me if it is a "good" transmitt antenna compared to
other types. (Ground plane, j pole, etc.)

the requirement: perform solder joints outdoors, in the winter,
without electricity, up a radar mast.

and the nominations are?

P.S. could a resistance-soldering rig do it, on battery power,in a
form factor that's small/light enough to haul up a radar mast in a
basket?

Part of the problem is that people will respond to his rudeness, if you
can't ignore it kill file him. He does it to disrupt the group and he can
only do so IF WE LET HIM. If we don't let him he can't disrupt the group.
Standard behaviour management.

If we just ignore his rude posts (or the bits of his few other posts that
are rude), the problem would go away. Sometimes some of the stuff I seen
responded to recently hasn't been that bad- maybe his engineering skills are
wanting but this is a forum to ask questions. If he could just stop being so
rude and negative I'd happily try and help him learn.

Thing is, he seems to see every mention of failure as a reference to him. I
can only assume he has very low self esteem. This does make helping him a
challenge. Pity we don't have an SEN teacher in the group- they would be
ideal to advise us on the best plan. He could draw up an IEP for him.

Gas (butane) or similar. Don't bother with anything that runs on AAs.

| P.S. could a resistance-soldering rig do it, on battery power,in a
| form factor that's small/light enough to haul up a radar mast in a

Why bother? Gas is light, cheap (dollar store) and you could even refill it
up there.

Stryped is kinda hard for me to figure out. He does seem to ask alot of questions that could be easily answered by researching some basics. One thing interesting is that he has gone to other news groups asking antenna questions to metal workers. Yet he has no time/ability to search for answerd with Google. I too have decided to "give up trying". I could surely change my decision if he showed some effort to learn the normal way, read/research, or just *do* something.

Agree Jerry reminds of an old adage

Give a man (person) a fish and he will be back the next day for another
(maybe 3 times a day - huh)

Teach a man to fish and he gains his respect and yours

We tried

Case closed

If you're doing it in a lawn just "sew them in" a good straight line so the radial is at ground level and then make some U shape pins out of whatever you have and pin them down. Stretch the radial as tight as possible before pinning. You'll be surprised how easy it is and how well it works and after about 2 or 3 mowings you won't be able find them, that is if have a lawn.

If you believe stating "No tumors were associated with less than 10
years of cellphone use" and "People with more than 10 years of cellphone
use suffered twice as many tumors as non-cellphone users" as you have
does not describe a step at ten years then you are stupid. I do not
believe it can be a step function as you proposed.

"No tumors were associated with less than 10 years of cellphone use."
Translation for feeble-minded people: The graph of brain tumors was
the same for users and non-users for the first ten years of use.

"People with more than 10 years of cellphone use suffered twice as
many tumors as non-cellphone users." Translation for feeble-minded
people: The graph of brain tumors for users and non-users started
to diverge after ten years with twice as many tumors in the user
group as there were in the non-user group.

Statement of fact for feeble-minded people: The above two graphs
were single-valued functions, i.e. no vertical steps existed.

Must be really hard for you to type with that straightjacket on.

how big are the joints?

soldering in the cold can be exasperating.

i use a small oxy-MAP gas torch. it can be a pain dealing with 2 cylinders
but it certainly gets hot enough.

I've made the same mistake - said "capacitance" when I really
meant "capacitive reactance".

> on this type of antenna?

Yes.

Popular Electronics in the 1960s and 1970s (Ziff Davis ownership) featured a
number of articles on constructing deep fringe VHF and UHF antennas. These
designs featured a similar pyramidal profile and element configuration.

You are very lucky that I still have one of these PE issues (for another
reference article).
Look for the Popular Electronic December 1971 issue -- George J. Monser
wrote the article of interest (page 40):
"Build a Mini-Pyramidal UHF TV Antenna". He reports pulling in UHF stations
(in San Diego), that were 185 miles away.

Mr. Monser lived in the Santa Barbara, CA area at the time of the PE
article.
His article references an earlier: "Build the Pyramidal TV/FM Antenna" that
was featured in the July 1969 issue of PE.
Supposed this UHF antenna design is a trimmed down version of that earlier
VHF design.

Hi Hank,

It seems it's not how, but how well. The how is trivial. The how
well is more a matter of a stock of ï¿½ inch which is sacrificed to
lumbering gross tools. Modern machines just make errors faster when
it is obviously within the scope of simpler hand tools and jigs. More
time has been expended in the sterile scribblings of what could be, in
place of actually getting it done.

Ross

I've tried to build antennas with this "technology" back in the 1960s. I
couldnt give you any specific referance to where design data is available.
But, it might be interesting to you to note that the stations being received
are in the direction that the Big V is pointed.
The fundamental concept is to feed the "Big V" at its "pointed end".
Then, the radiating elements get increasingly longer as the feed line
spreads. When the elements are about right for radiation at the frequency
of interest, the majorty of the signal is either radiated or received. In
addition, each succeeding element is reversed in phase. Since the VP of the
transmission line is about the same as velocity of the radiated wave from
the previous element, a Null is created in that direction (away from the
pointed end).

When I learned about the LPV antenna, I considered it to be more practical
for the TV frequencies. They work with elements 1/2 wave long and when the
elements are 3/2 wave long. That works quite well with TV frequencies.

I'd bet you can get the attention of some "real" antenna designers in this
news group to explain the Log Periodic Antenna design. I was never a
really good antenna designer and havent worked in antennas since 1969.

Jerry

hi

Realize this is perhaps a long shot but cavities and filters arent my bag...

I live in a 12 story apt building that has a master tv antenna

the standard tv type but rather a bit larger than usual

it's fed via coax and not sure whats on the roof but asume some sorta dist amp

on each floor is a bunch of spliters to break the coax into 'ports' for each apt bout 6 per floor

just wondering a really crazy wackey thought

would their be anyway i could use this as a hf antenna while somehow isolating it from doing damage to the tv's , amps ???

it would be basically to be a low impact stealth install obv if i install anything the buidlng mgt would be involved but people passing on the street wouldn't know

Hi OM,

Doing the same thing to the plumbing may be more successful, less successful, or probably undifferentiated (such are the variety of answers for the original query's outcome). But one thing about this alternative, you would be at less risk to ruining someone's evening in front of the tube.

Who knws undeed! It could pcost as much as the national debt of
Liechtenstein which isn't big enough to field a full sized 16 KHz
superhip antenna for communications to their solar powered submarine
fleet. But if the fate of whirled peas hinges upon their sacrifice,
cost be DAMNED!

Richard gave you an honest answer, but didn't elaborate. If you try to push RF back up the center conductor of the
coax, it will fry the first device it gets to, and not do much else. If you try to feed the shield against some other
"ground", then most of the "antenna" thus formed will be inside the building, and therefore not much of an antenna, and
will be horrible on receive as it will be close coupled to every noise source imaginable (can you say switching power
supplies in every electronics box known to man plus motor controls etc., etc.). So, try it, but be sure you have good
legal representation lined up first.

Or much more likely, a "culling" by customers / compettiors.

So why would you expect this particular geographic environment to provide
unique educational stimulus, above and beyond the crystal meth dealers of LA
or the rock cocaine vendors of Chicago?

After they sobered up, they realized that the Brazilian Renaissance only
changed the course of world thinking for 12 minutes.

But you just cited an example of profs and students organizing a research
expedition to Rio to count the sewer rats, or was it to study how the sewer
rats count?

Well, if you have "stock", and it's a small thing of which you're making many, you get a method that allows both measured increments and a locking system. You do a test, and adjust, so that once it's good enough, you just shove the stock in and slice it.

If it's a one-off that has much time/money/work already into it, you use the same arrangement but plan and measure as best you can first.

The "standards" for RF safety assume that heating is the only thing
that affects health.

The standard as tested and applied will prevent problems due to
heating - and make the world a safer place for Jello.

I seem to remember at least one case of a researcher in the US turning
up some evidence that low frequency magnetic fields inhibit a bodies
ability to either use or produce "T" cells.

Personally, I don't think there is enough research into it. (and
there isn't likely to be enough)

>Standard behaviour management.

Very good points.

Having posted what appears to be on the surface a technical item
regarding the construction of capacitors for an ATU, it seems that
Bean has done no calculations whatsoever regarding the design.

Even simple back-of-the-envelope calculations would have pointed up
the the critical areas of component performance, which, together with
an appraisal of the limitations of his chosen resources, may have led
to a more realistic redesign. OTOH it may have indicated or confirmed
the correctness of his original approach. But we'll never know.

But did he respond accordingly? Instead of being an interesting
technical discussion, it has become yet another stick with which to
beat selected responders - the 'gentlemanly traditions' disappearing,
if they ever surfaced at all, very rapidly. One is left with the
strong impression that the original posting wasn't meant to be a
technical discussion at all, and another poster's comment elsewhere
about 'the cycle repeats' appears very apposite.

I note that you have already mentioned what could well be the achilles
heel of Bean's choice of components, and one which I was trying to
gently steer him to in my initial contribution. But it seems that it
is more fun to wield the stick rather than undertake any real design
studies. Ah well.

A point to be made: The entire propagation path betwix San Diego
and Santa Barbara is over salt water (AKA the Pacific Ocean.)
There's been many reports of Shack-On-The-Hip operators bringing
up repeaters in San Diego from Santa Barbara (and versy-vicey.)

Good tropo here is probably a bigger factor than good antenna(s).

975. How can this be?

Newsgroup: rec.radio.amateur.antenna
Date: 2005-01-14 15:46:27 UTC
From: Ken Bessler <kg0wx@NOSPAMyahoo.com>
Message-ID: <nPRFd.18091$ph.11198@okepread01>
Source record: 83514

Several months ago I had a temporary U/VHF base antenna.
It was a MFJ-1729 dual band mag mount stuck to a radial
plate on a 30' mast. I was feeding it with about 36' of RG58
that was made up of 3 sections, joined with SO-239 barrels.

I thought it was working great because I could hear a friend
on the input to a repeater some 50 miles away (he lives very
close to the repeater).

I improved the antenna with a mono band vertical, better
coax & more mast. My math says I gained 10' in altitude
and 2.7 db overall (factoring in new coax & better antenna).

All of a sudden my new, better & higher antenna could NOT
hear my friend! WTF? I figured it was a band opening and
forgot about it.....

Last week the ice storms caused a branch to fall, ruining my
antenna. Due to $$$ shortage (replacing my HF rig), I opted
to go back to the temporary setup. The tip of the antenna is
10' lower and overall gain is 2.7db less.

I can hear my friend again!

I don't get it - the premium antenna worked better except for
hearing my friend, where it worked worse. Anyone care to offer
an explanation?

Ken KG0WX

> an explanation?

Perhaps there was constructive multi-path interference
on your friend's signal at the location of the lower
antenna but not at the location of the higher antenna -
or vice versa. Or your friend was not located in the
plane of maximum gain of the higher gain antenna. That
2.7 dB of extra gain at one take-off-angle comes at the
expense of reduced gain at a other vertical angles.

Several possiable casuses. Your friend started using lower power for a
while. The patern of the new antenna had a null in your friend's direction.

Hi Ken

Location, Location, Location and of course Take-Off Angle!

I had to lower a 55 foot antenna down to around 45 feet to hit our local repeater only 3 miles away. At 55 feet it was blocked by a microwave antenna, at 40 feet it is blocked by several steel framed buildings. At 45 feet, there was a hole I could squeek through so to speak.

Now, if I switched from a 5/8 wave to a 1/2 wave vertical, I had to go all the way down to around 30+ feet to find this hole again.

For instance, if an antenna is resonant on 460 MHz,
multiply all the dimensions by pi to make it resonant
on approximately 146.4 MHz.

All signs of insecurity. If Gareth was sure of himself he could debate /
discuss at a technical level. I can't ever actually recall him doing this.

I'm sure there will be a name for his condition, probably even treatment.

When I divided 460 by 146, it was so close to pi that I
couldn't resist. We have a cartoon on the wall here at
the GED center that was lifted from a MENSA publication.

The setting is a restaurant where a man has just asked the
waitress, "How much is pie?" She responds, "How much is pi?
Last I heard it was
3.14159265358979323846264338327950288419716939937510582097 49..."
There are a couple of hundred additional digits on the cartoon.

"It is the first landing of a spacecraft on the moon of another
planet. And Titan is no ordinary moon, but a body larger than the
planets Mercury and Pluto, and almost the size of Mars."

...

"The possibility remains that a design flaw in Cassini's radio
receiver system will hopelessly scramble the data. Engineers
anticipated that signals from the wind-tossed Huygens would vary
widely in frequency and strength, and thus compensated for it in the
receiver's design. But they had failed to take into account frequency
shifts that would also throw off the timing of the encoded data,
leaving it a garbled mess.

"In early 2000, an ESA engineer recognized the problem. Finally, ESA
and NASA engineers found a way to reduce the frequency shifts to
acceptable levels by altering the trajectory and orientation of
Cassini during the critical maneuvers."

This is a joke, right?

I am serious with the question. Will "scaling it" for a bottom band of
say 108 mhz make it "less efficent" at higher band?

Walter Maxwell wrote:
But a ground plane antenna suffers no
> ground losses, so using as many as possible only applies to radials
on
> or in the ground.
>
> Walt, W2DU

Or low to the ground in terms of wavelength. But you wouldn't have to
use
"as many as possible". With most VHF/UHF ground planes, they are
usually
several waves up off the ground, and ground loss is very low. But if
you
take a low band ground plane, say 1/8 wave off the ground, you will
need
quite a few more radials than 4, to equal the benchmark of 120 radials
on
the ground. According to charts I've seen, and also backed up with real

world results, a ground plane 1/8 wave off the ground will need appx
50-60 radials to equal the 120 on the ground. At 1/4 wave up, about
8-10
or so. At 1/2 wave up, 4, 3, or just 2 radials will all work fairly
well.
Of course, I would always prefer four, over two. Even if ground loss
was
not a factor due to being high up, the decoupling of the feedline is
better with four, than two. In real world tests on VHF, I've noticed a
noticable difference going from 4 radials, to say 8 , or even 10. And
that was several waves up...So adding more radials does continue to
improve the antenna. Probably more due to the improved decoupling of
the feedline, rather than lower ground loss I would suspect...I've
heard
many a tale of disappointed hams having poor results with "low" ground
planes, and not enough radials. But thats usually on 160,80, or 40
meters.
Actually, I don't know of any ground plane users on 160, but I have
heard of quite a few on 80m..Four radials at 10 ft up on 80m, is better

than four radials on the ground, I think, but not by a large amount...
Ground loss will be fairly substantial if the ground quality is
mediocre.
In my HF experience with them, the lowest I would use four radials, and

expect *good* performance, would be at 1/4 wave up. When I would lower the mast to 1/8 wave up, you could see quite a difference. That was on 40m, where I ran a full size GP at 36 ft at the base, on a pushup mast.

BTW, that was a great DX and late night antenna on 40m...I also had a 24 volt relay to switch a base loading coil in for 17m use as a 5/8 GP. I changed bands here in the shack, by unplugging the transformer, for 40m use..That bypassed the 17m coil.

Not exactly - just a dash of Aquarian humor.

> I am serious with the question. Will "scaling it" for a bottom band of

If a uhf discone is designed to cover 400-500 MHz, for instance,
when you scale it to a vhf center frequency of 108 MHz, it will
cover approximately 96-120 MHz.

Jamie:
The (gas) butane soldering irons are the best for what you want..... the
problem with battery operated soldering irons is that they do not produce a
lot of heat for any length of time.... and usually when you only have a few
more joints to solder, the battery DIES. With a butane soldering iron,
when it runs out of gas you just refill it and you are ready to solder again
in a few minutes.and if more heat is needed just turn up the gas and install
a bigger tip.

Once again, Mr.Reay is brandishing his card with
the "insecurity" sneer upon it.

That Mr.Reay feels the need to repeatedly initiate
personal remarks of an aggressive character, personal
remarks that cannot be taken as "debate / discussion at
a technical level", would seem to suggest that it is Mr.Reay
who is insecure, do you not think?

Jonesy -

Yes

Once I found out where he lived .. that became apparent. Of course, he made
no mention of this
signal path in the PE article (impressing the teenager at that time of the
deep fringe coverage of the design).

:-)

Nah-- Think is is referred to as " Fresnel Zones", and other
nomenclature- It has to do with multi-path - phase relationships
of the recieved signal- similar to the drive down a country road
at midnight, listening to an A.M. broadcast station (DX) fadeing
in-out - if you measure the distance between the 2 fades, it
equals 1/2 wavelength ! this effect works also in the verticle plane!
and, at vhf- the effect is quite noticeable in the fades (every 40
inchs at 2 meters, and about 18 inchs on 450) has to do with the
multi path signals arriveing in phase, or out of phase (cancelling
each other)! as info-- Jim - NN7K

Have a discussion with building management. You management has to
accommodate the satellite dishes, per earlier FCC ruling.
You may get an understanding management team. They could actually make $$
if they updated the system for DishTV (or DirecTV). I have a friend who has
his own business (design, install, maintenance) full-time in Chicago area
for a number of management companies (apartment complexes; planned
communities). It is a good alternative to cable TV proposals or old MATV
systems.
Management companies like it .. since there is only one dish and head-end
for building (does away with porcupine dishes on side of building and
patios).

I don't think that will do. They barely work indoors.
Small little torch is the only way to go.

Also, consider : low temperature solder-- can be melted with a match-
tho NOT advocating THAT technique, would recommend that with a butane
iron, or torch in inclemate weather! And, have used the butane irons
in blizzard conditions, in the Sierras (repairing equipment for the
railroad), useing these. highly recommend them for use in adverse wx!

If you can use them in those conditions then no question they're the best.
Everything I have heard about the 4 AA irons is not confidence making!

GB

don't mean this to sound rude but perhaps ....i overlooked a thing or 2

i must be misssing something, so lets say my building puts up a sat dish, which btw is already up there

how does this relate to my post? do you know of some way to make a direct tv dish work for hf? ohh while simul connected for tennants tv use?

Hello Glenn,

I've finally found time to review your QFH design, and find it quite
close to that which I designed for the wx sats, now the polar-orbiting
NOAAs (TIROS-N).

The design for the NOAA wx sats follows the data at the bottom of Page
22-14 in Reflections 2, in which diameters D1 and D2 at 137.56 MHz are
34.0 and 37.7 cm, respectively. Yours are 35.6 and 36.4 cm,
respectively. The perimeter dimensions P1 and P2 for the wx sats are
221 and 244 cm, respectively, while yours are 222.8 and 236.2 cm,
respectively. The height of the longer of the two bifilars in the QFH
of the wx sats is 0.260 lambda, or 56.7 cm. I was unable to determine
the height of your model.

The element tubing diameter in the wx sats is 1.918 cm, or 0.755",
while yours is 3/8" (0.375"). We actually used 3/4" tubing on the NOAA

wx sats.

Have you measured the terminal impedance of the quadrifilar? If it is to radiate optimum CP at the operating frequency the impedance must be very close to 50 ohms. Observe the Smith Chart plot, Fig 22-10 on Page 22.13, and note the cusp in the impedance plot at 0.95 +j0. During the development phase of the QFH I found that this impedance proved the self-phasing was working properly and was achieving excellent circular polarization. If the cusp was off from this point the circularity was jeopardized, as proven by measurements.

The reason I mention this is because one of the vital parameters in obtaining the + and - 90ï¿½ phase relationship between the two bifilars to obtain the self phasing is the diameter of the elements. It is the difference in the inductance of the elements, due to the difference in physical lengths, that obtains the 90ï¿½ phase relationship, and the diameter of the elements is crucial to the correct element inductance. So if the cusp of the swept input impedance plot is very far off from 50 + j0 you can expect that the circularity to be jeopardized.

Now to answer you original question concerning the use of copper or stainless steel, I would not expect to see a significant difference in performance between the two, especially considering the diameter of the conductors. The difference in loss resistance between the copper and stainless steel would be insignificant at this frequency when considering the diameter involved.

Please let me know if I can be of any further help.

Walt Maxwell, W2DU

Joel Kolstadt wrote:
"Hmm...how about...three! ground radials?"

Three radials should be fine where they are elevated to such height that they capture all the electric lines of force from the vertical radiator.Radials are balanced and their currents travel in offsetting directions. The radial system does not radiate itself because of its offsetting balances. Elevated radials must shield the earth from induced current. This requires few radials when the radials are far above the earth, but where the radials are near to the earth, many radials are needed to capture all the electric lines and shield the earth from lossy currents.

The number of radials and their effect on pattern and efficiency of radiation from a vertical antenna is well addressed by ON4UN in "Low-Band DXing". This is found in Chapter 9 of my 2nd edition. Choose the efficiency and elevation angle you are willing to accept ftom the graphs and tables presented.

Best regards, Richard Harrison, KB5WZI

You're quite correct, Mark, but when I mentioned 'ground plane' I'm thinking in terms of VHF/UHF, with the antenna many wavelengths above ground.

Thanks for clarifying my omission of terms.

Hello Glenn,

I've finally found time to review your QFH design, and find it quite
close to that which I designed for the wx sats, now the polar-orbiting
NOAAs (TIROS-N).

The design for the NOAA wx sats follows the data at the bottom of Page
22-14 in Reflections 2, in which diameters D1 and D2 at 137.56 MHz are
34.0 and 37.7 cm, respectively. Yours are 35.6 and 36.4 cm,
respectively. The perimeter dimensions P1 and P2 for the wx sats are
221 and 244 cm, respectively, while yours are 222.8 and 236.2 cm,
respectively. The height of the longer of the two bifilars in the QFH
of the wx sats is 0.260 lambda, or 56.7 cm. I was unable to determine
the height of your model.

The element tubing diameter in the wx sats is 1.918 cm, or 0.755",
while yours is 3/8" (0.375"). We actually used 3/4" tubing on the NOAA

wx sats.

Have you measured the terminal impedance of the quadrifilar? If it is to radiate optimum CP at the operating frequency the impedance must be very close to 50 ohms. Observe the Smith Chart plot, Fig 22-10 on Page 22.13, and note the cusp in the impedance plot at 0.95 +j0. During the development phase of the QFH I found that this impedance proved the self-phasing was working properly and was achieving excellent circular polarization. If the cusp was off from this point the circularity was jeopardized, as proven by measurements.

The reason I mention this is because one of the vital parameters in obtaining the + and - 90ï¿½ phase relationship between the two bifilars to obtain the self phasing is the diameter of the elements. It is the difference in the inductance of the elements, due to the difference in physical lengths, that obtains the 90ï¿½ phase relationship, and the diameter of the elements is crucial to the correct element inductance. So if the cusp of the swept input impedance plot is very far off from 50 + j0 you can expect that the circularity to be jeopardized.

Now to answer you original question concerning the use of copper or stainless steel, I would not expect to see a significant difference in performance between the two, especially considering the diameter of the conductors. The difference in loss resistance between the copper and stainless steel would be insignificant at this frequency when considering the diameter involved.

Please let me know if I can be of any further help.

There are various methods. First, you have to specify what kind of equipment you are using. You never did say. BTW, American speakers spell it center. We left England so we were free to do it a better way.

Problem solved by using the bread knife. (New
replacement purchased for SWMBO)

The problem with a lawn edger is the heavy clay that
adheres to it, resulting in an unsightly hole rather than
a neat slit.

You have a lot of nerve calling anyone mentally screwed up, Doug.

Questions:

1. How is the court ordered shrink working out for you?

2. How's the court ordered job hunt going?

3. How's the court ordered wage withholding going?

4. Have you made the rain report for jamming repeaters again, Doug?

5. Have you threatened to kick anyone elses ass, only to have them show
up at your section 8 slum and prove what a fucking coward you are, maggot?

Go lay down by your bowl, dogie.

Your approach (IMHO) will not work and should not be pursued.

Rather, have a discussion with building management. You would want to run
ONE cable from your apartment to roof and your antenna on the roof. Your
busiling management has likley been appraoched by other tenants (for
mounting satellite dishes - erlier tie-in) AND by cellualr phone companies
looking to place antennas on their roof. However, they are waving $$ in
front of their eyes (which should reduce your rent or increase their profit)
.. you pay rent (eave your $$) during discussion.

I've had good luck with the kester 62/36/2% silver stuff, which is eutectic.

Many many years ago, I had some luck with a indium-bismuth solder paste in syringes from Indium Corp. Haven't fiddled with any of their stuff since then.

Radio Shack sells a bag of little peices of tape-form stuff. Never got it to work well.

"Sarge" <sarge43@NOSPAMev1.net> verbositized:

>I used a lawn edger....

Then you had dirt sprayed everywhere!

Using the meat cleaver I stretched the wires above ground first, slid
the wire through an eyehook and cut along the edge of the wire. The
eyehook did the burying of the wire as I moved along the ground.
When I was done, I was done! And the yard suffered no damage!
And it probably went a whole lot quicker than wrestling with a lawn
edger, getting the wire into the slot and holding it in place while
you covered the hole, and got rid of the dirt that sprayed all over
the place.

Heh, heh, after presenting the play, "Annie", this year
(I was FDR) the Madison County Arts Council asked for ideas
on a play for next year that would employ a bunch of kids.
I suggested, "Lord of the Flies", which met with a very
cool reception. :-)

Right you are, Mr. bean. Some individuals can't seem to separate their personal from their business lives. They need to assign a dollar value to everything. Many of these people, when not at work, do nothing as they dismiss most leisure time activities as an inefficient waste of man-hours.

No. But, then again, it isn't there so I wouldn't have.

If you meant amateur, that work doesn't not mean 'bodger'. Just because you
are doing something for fun is no excuse not to do it well.

Hi all,
newbie question here...sorry if its covered elsewhere. My radio has a clip terminal for an ext. antenna, and wants to see 500 ohms. I want to put a transformer at the longwire for the coax feeder to show it 50 ohms for the trip into the house...will it work if I put another transformer in the house to get it back to hi-z?
The transformers will be home made ferrite coil jobs as described in John Bryants excellent article.
TIA
mike

How do you know the impedance of your longwire is 500 ohms?
If it is unterminated at the end, the impedance is definitely
not 500 ohms, except by complete accident.

I have a selction of different sizes of "soldering Coppers" that I heat
with a torch.
They work good and I can control where I put heat. They are however not
easy
to heat with the torch.

The "cold heat" soldering iron works on the same principle as
an electric welding machine. Thus, there is the germ of a good
idea there. How about a soldering iron using the same principle
as the "cold heat" soldering machine except run off of 110VAC?
It could be transformer isolated, run on low voltage, and thus
be perfectly safe, but with a nearly unlimited source of power
to overcome the battery power limitation.

Easy! Just say how long is the wire, at what height, at what frequency, and the impedance of the ground connection, and lo-and-behold, all will be revealed by a calculation which will involve arithmetic. And arithmetic is an unwelcome subject on this newsgroup.

Not that the resulting value of Z = X + jY will be of much use to you. What plans do you have to do with it?

In a fraction of the time expended in vague questions and obtaining even more vague replies, why not erect the wire, as you propose, and connect the capacitor in parallel to see what happens.

But you may save even more time by connecting the capacitor in series.

Good luck with your experiments.

Reg.

Well, I went to my first hamfest and I am now the owner of an alinco dr 590 dual band radio I wish to use as a base station. I must now decide where to locate an antenna. I have a tv town that I could mount it on but It would require about 70 feet of cable and fishing of the coax through some insulated walls upstairs. Or, I could mount the antennas to my vinyle chimney somehow and only have about a 20 foot run. But how would I get the cable inside my house? The only way I see is drillling a hole in the side of the house which I am not crazy of.

What is the best/most econmical cable to use? How would you do this installation?

Also, I dont have a power supply. I do have a deep cycle battery. Would it be improper to use this in my house as a temporary measure?

By the way this radio has two antenna inputs. I think I will use two different antennas. I am thinking of building a beam for 440 and using a j pole or ground plane for 2 meters.
I appreciate any advice you could give me!

Any beginning ham is going to have a million questions -- have you considered getting a copy of the ARRL Handbook for Radio Amateurs? You can get it at www.arrl.org in their product store, or from www.amazon.com for a probably lower price. It will answer just about any question about setting up your station, including all of the questions above, and the million or more you'll have in the coming days :-)

Have fun!

Got the answer from a friend. He explained a little bit about antenna theory and sent me away to hack away at my antenna (and it worked).

Thanks to any who may be writing a response to me though. Mike

Just hook the longwire to the radio directly at first.
Then run a ground wire to the [gnd] terminal.
(assuming its receive only).
You can also play around with an antenna tuner too - pick one up at a
hamfest for a few bucks.
But its also fun to play with xfrmrs too! You didn't mention the freq you're
listening to or how long the wire was, so you don't really know the
antenna's impedence, so an antenna tuner looks better and better.
Have fun!

plain old 60-40 rosin-core electrical solder has worked well for me - got
mine at a hamfest on a half-pound roll.
the silver stuff (I believe) melts at higher temperatures - and higher
temperatures are not good for electronics.
eutectic (if my memory serves) just means it's either solid or liquid - and
won't just 'soften' - like ice and water.

Silver-bearing solder is for use with silver plated terminal strips
(such as Tektronix used to use); silver in the solder prevents the
silver on the terminals from being dissolved by the solder and ruined.

Hi Group,

I have an Venture maxi 8500 actulator I picked up for a Sate-disk project. The system is about 20 years old.

The motor does not want to run off of 13V, it will sometimes start but most of the time not.

Maybe someone on the group recalls if these motors are 24v or higher? The motor resistance is about 2.5 ohms.

If anyone has a schematic of the gear box, that would help, other than the motor power wire set, there is a green and brown wire set in a shield coming down the cable, any thoughts on what these are for?

Tnx de KJ4UO..

1059. cable modems?

Hi Group,

Do cable modems modulate the data on a carrier and send down the line or do they just use baseband?

If they are carrier control, what frequency do they operate?

Thanks,

De KJ4UO

They do not operate (downstream data) on standard cable TV video channels
used by the local cable provider, but usually for upstream select from
available bandwidth below 42 MHz) The service is bi-directional (which
requires upgrades to some older CATV equipment to support this
functionality)

Cable Modems since about 1996 operate under the DOCSIS standard (there is
also a Euro-DOCSIS)
http://www.cablemodem.com/

The three successive versions of the DOCSIS cable modem specifications:
DOCSIS® 1.0, DOCSIS® 1.1, and DOCSIS® 2.0, provide increasing levels of
capabilities and functionality, while maintaining multi-vendor
interoperability and full backward and forward compatibility of DOCSIS.
a.. DOCSIS 1.0 specifications include technology that was available in the
1995-1996 timeframe, and have become very widely deployed around the world.

b.. DOCSIS 1.1 specifications provide improved operational flexibility,
security, and Quality-of-Service (QoS) features that enable real-time
services such as voice-over-IP telephony (VoIP), interactive gaming, and
tier-based services.

c.. DOCSIS 2.0 specifications provide dramatically increased upstream
throughput for symmetric services. DOCSIS 2.0 provides 30 Mbps of capability
Digital data signals are transmitted over radio frequency (RF) carrier
signals on a cable system. For two-way communication, there is one carrier
signal that carries data in the "downstream" direction (from the cable
network to the customer), and another that carries data in the "upstream"
direction (from the customer to the cable network). Cable modems are devices
at the subscriber premises that convert digital information into a modulated
RF signal in the upstream direction, and convert the RF signals to digital
information in the downstream direction. Another piece of equipment, called

a Cable Modem Termination System (CMTS), performs the converse operation for multiple subscribers at the cable operator's headend.

Typically, a few hundred users may share a 6-MHz downstream channel and one or more upstream channels. The downstream channel occupies the space of a single television transmission channel in the cable operator's channel lineup. It is compatible with digital set-top MPEG transport stream modulation (64 or 256 QAM), and can provide up to 40 Mbps. In DOCSIS 1.0 and 1.1, the upstream channels can be up to 3.2-MHz wide, and can deliver up to 10 Mbps-per-channel. In DOCSIS 2.0, upstream channels can deliver up to 30 Mbps over channels as wide as 6.4 MHz. A media access control (MAC) layer coordinates shared access to the upstream bandwidth.

Google on DOCSIS for thousands of references and technical documents.

The eutectic alloy is the one which has the right proportions to give
it the minimum melting point for a given set of constituent metals.
I've only seen the word applied to binary alloys, but I suppose it
could be applied to alloys of 3 or more metals, too. I'm not sure if
that's a proper use of the term, however.

A side effect of using the eutectic alloy is that there is a
distinctive melting point. When the alloy is non-eutectic, there are
separate solidus and liquidus points, between which the alloy is just
more or less "slushy."

There is no slushy region when a eutectic alloy melts. This sounds
like what Hal was describing above.

Sunlight is Electromagnetic radiation and hardly anybody seems to
mention this when talking about cell phone sand RF safety. Sunlight
also causes heating effects and lots of it. (I know I enjoy it) 1000W
per square metre of radiation hitting the earth on a nice day. That's
a bit more than a cell phone emits I believe AND it contains the
ionizing type of radiation too which is known to cause cancer of
course.

I believe that if there is something to this cell phone thing that it
may be from the electric part of the near field.

I'm certainly not too worried because they seem to have too hard of a
time proving anything. Unlike smoking and lung cancer anyway.

my 2 cents.

I would drill one hole, if you really don't want to drill two, and use a diplexer. Cable losses are worth saving for that - its no big deal drilling a hole - much more of mounting aerials safely.
Even better drill a 30 to 40 mm diameter hole, sleeve it with waste pipe, then run whatever cables you want, when you want. I guess you won't like that though !
Always use good quality cable - its a cheap "upgrade" - no point in spending 500 to 1500 on a superb rig and wasting half its power in cable losses ! UR67 or RG213 at least - in UK I use Wesflex 103.
A power supply is a good investment - secondhand they are not expensive, but many use batteries and chargers so its an option.
Wire it up safely ! Fuses where appropriate etc and thick power cables to minimise losses there - no "bell wire".
As the other poster said - borrow the ARRL or similar from the library or buy it new or secondhand - the contents don't change too much too fast........

Hope that helps,

Welcome to Amateur Radio !

Nick

The eutectic combination of tin and lead is 63% tin, 37% lead. 60/40 has a slightly higher melting point, and unlike the eutectic alloy, has a plastic stage between liquid and solid. Consequently, 63/37 is a better choice for solder.

1070. vertical antenna choices

Newsgroup: rec.radio.amateur.antenna
Date: 2005-01-16 13:16:34 UTC
From: Jerseyj <jerseyj69@comcast.net>
Message-ID: <jerseyj69-935C89.08163416012005@comcast.dca.giganews.com>
Source record: 83459

Hi all,
Seems like there is a bewildering choice in vertical antennas. My "dream antenna" would be:

Not higher than 35 feet
Requires no guying
covers 10-160 including WARC bands
Has a "reasonable" bandwidth in each band with
less than 2:1 SWR (I know this is a tough one to include 160 for)
No radials
Automatically tunes for each band (meaning I don't have to go
to the antenna to do something to change from 10 meters to working
on 40 Meters)

There seems to be a large number of choices, none of which does quite all of that (maybe I missed some, suggestions are welcome). Seems like I have at least some good choices going 10-80 but when I include 160 they go away.

I'm interested in any suggestions or experiences with verticles as noted above.

Agreed. From my vague recollection, the researcher that was seeing
effects in the immune system from low frequency emf exposure
attributed it to the magnetic field, and was looking at power line
frequencies.

There is some epidemiological evidence that shows a positive
correlation between certain types of cancer, leukemia in children and
nervous system & brain cancers in adults, and Weak LF EMF.

The standard test when it comes to RF safety is for tissue heating - a
cube of gelatin is exposed to the field and heat rise measured. That
assumes that heating is the only ill effect of RF radiation
(forgetting for the moment obvious stuff like RF burns or ozone damage
etc.) - it is possible that there are other, less active, or slower
developing deleterious effects. And that was my point . . .

Like the new approach to pharmaceutical safety in the US - clinical
testing is expensive - it will turn up in the epidemiological evidence
or actuarial statistics eventually - after industry has a chance to
make a profit.

It is unrealistic to expect government to initiate the research until enough people become aware of a problem. That only happens when something is self-evident to a large number of people; and that, in turn, depends on the media to correctly report it.

Jerry, KISS

The best vertical is an approximately vertical wire, rod or mast, as tall as possible, with a set of shallow-buried ground radials, a dozen or so in number, with a length roughly equal to antenna height. The whole contraption, if you can manage it, being well away from man-made buildings and dense tall trees.

Any experimental modifications, such as loading coils, will result in very minor changes, hardly noticeably better on some bands but inevitably worse on others.

The most important component in the system is always the tuner, next the ground system, and finally the antenna wire. KISS again!

thanks for the input!

the antenna I ve started in a 60 ft. 14g. copper wire, up in the trees
away from the house. I,d like to feed this into the house with rg58. my
radio tunes continuosly from 3 to 30 K, but I have also been mucking
around with some crystal sets which are more limited.

I,ve read that the antenna impedance is likely to be around 450 ohms,
which would be fine staight to the antenna connection on the receiver I
guess, but I would like to use the coax to protect the signal from all
nasty stuff my house generates (and to protect the house from the
potentially nasty stuff my antenna might!). So I would like the signal
to go from 450-ish to 50 and back to around 500...

Thanks again...and dont worry about me not having fun...;)

1086. Tuning an AEA Halo on 6m?

Newsgroup: rec.radio.amateur.antenna
Date: 2005-01-16 19:21:07 UTC
From: Ken Bessler <kg0wx@NOSPAMyahoo.com>
Message-ID: <C8zGd.18246$ph.7545@okepread01>
Source record: 83325

I got a AEA halo for 6m and put it up. Worked good but the
low SWR point was 51.000 with a 1mhz 2:1 bandwidth.

I wanted to adjust it so I got a 1:1 SWR at 50.500 so I took
it down and loosened the loop overlap screws. I then stretched
the loop out 2", figuring longer = lower freq.

The low SWR point CLIMBED 800 khz!?!?!? WTF?

I pulled it back down and made the antenna *shorter* than I started
and bingo! It now shows 1:1 SWR at 50.500 mhz yet still shows
acceptable SWR on the local 6m repeater's input (51.130). 52.525
is out - SWR too high. :-(

Will someone please explain why this antenna seems to defy
conventional tuning standards?

Ken KG0WX

Hi Airy

In my particular case I used the eyehook to hold a split tube.
But the eyehook can be bolted in, bent downward toward the blade and
manage to keep the wire at least 2 inches underground.

Also, if you hold the cleaver at a 45 degree angle, with the eyehook
at the top, you are still setting the wire about 2 inches below the
surface.

In practice, I lay the cleaver across the uncut grass, whack it with a
rubber mallet, tip it up 45 degrees and tap it with the mallet through
the cut. Before tilting it back down for the next grass cutting whack
I tamp the sod behind the head of the blade to hold the wire in place
so it don't pop back out.

I buried 3,500 feet of radials in one afternoon using the rubber
mallet and cleaver with eyehook. I only added the split tube because
I kept getting the eyehook caught in the sod which required an extra
whack with the mallet. After sticking the tube through the eyehook,
not only did I not get stuck in the sod, but the wire would stay in
place without jumping out occasionally also.

>choice for solder.

I understand that there's a tradeoff involved. The 63/37 eutectic has
a lower melting point and no plastic stage, and some people feel that
the latter reduces the risk of 'cold' solder joints somewhat. On the
other hand, I've read that the 60/40 alloy is somewhat superior in its
"wetting" property - it adheres and bonds to some base metals better
than the eutectic does, and might make superior joints as a result.

I tend to prefer the eutectic, or a eutectic modified with 2% silver.

Also, there are things like stainless steel, and aluminium that don't
like regular 60/40 solder-- however silver solder will solder to
stainless antenna rods (repair antenna whips, ect). and aluminium
is easy to solder to, but consider : 1) that aluminium oxide WON'T allow
solder to adhear to it, and that : 2) aluminium oxidizes almost
immedietly ! The way to solder to aluminium without special solders/
fluxes is to scrape the surface, and then immediatly apply hot iron and
solder. Then solder will adhear to it! As a side note, concerning
the oxidation of aluminium, consider that the silver powder in fireworks
is powdered aluminium! Have a friend , whose dad told of his experience
with it (powdered)-- was used to make aluminium based paint- he was told
by his boss to get rid of it-- threw it into an incinerator-- and,
KABKOOIE ! as info, Jim NN7K

1091. DO YOU WANT TO OBTAIN MANY DOLLARS?

Newsgroup: rec.radio.amateur.antenna
Date: 2005-01-16 21:10:08 UTC
From: darting@latinmail.com
Message-ID: <e12fe651.0501161310.2574ca6e@posting.google.com>
Source record: 83330

YOU WANT TO OBTAIN MANY DOLLARS ?
I've been trying to figure out the way to make extra money in the internet, checking news groups and ads. It's not easy but I try to keep an open mind to opportunities. In these websites you would find messages like the one described further below. The message got me thinking:This is just a chain, I don't buy it. But, what if it works? It's not something new. People have been doing it for decades and I've never heard of anyone that have acctually made some money out of it. But, what if it works? When you really think obout it, this is a real job. I finally made up my mind and here I go. If you made up yuour mind too, or if you're still giving it a little more thought, keep reading. It won't be easy. Putting this message on every single website that you can think of, like news, newsgroups and ads will be necessary. The more you do it, the better for you (and for me too, of course), that's why it's a real job. It'll take several hours of advertising and promoting.
This chain is different because it doesn't deppend on five or ten persons to whom the masseges would have to be sent by tradditional mail. With the internet, the message is sent worldwide, available to thousands and someone (like me) it's going to go for it. Finally, did you think how much you're going to learn from this kind of task so you can use this knowledge on future jobs or projects?
Now my name is the last one on the list, where, if you decide to go on, you'll put yours at the end leaving my name as the one before last. I wish you good luck, because part of this luck is for me too.
This is the message I found:
"A few days back, when I was visiting news websites, just like you are now, I saw an article, very similiar to this one, saying you can make thousands of dollars in just a few weeks by investing only US$6ï¿½ï¿½! I thougt: "Oh no! Another fraud?" But just like most of us, I got very curious and I kept reading. The article showed six names and addresses for you to send US$1ï¿½ï¿½. Then, you have to write your name at the end of the list replacing the one on #6 and send the article to at least 200 "newsgroups" (there are thousands of these all around the world). There's no trick, that was it.
The big difference between this chain system and others is that you have a list of six members instead of five. This means that your average proffit will be fifteen times higher!!! After thinking it through with my friends, I decided to give it a try. After all, I had nothing to lose but six stamps and US$6ï¿½ï¿½, right?
I was worried about the whole thing being legal, so I contacted the Correo Central de Chile and they confirmed this chain is completely legal!!
So I invested my US$6ï¿½ï¿½.....GUESS WHAT!!!... seven days later, I

started to recieve money by mail!!! I was really surprised!!! I still thought this would end in a few days, but the money kept comming!!!
The first week I made from US$20ï¿½ï¿½ to US$30ï¿½ï¿½. By the end of the second week, I had made a total of US$1.000ï¿½ï¿½!!!!! By the third week I got more than US$10.000ï¿½ï¿½ and I was getting more. This is my fourth week and I've made over US$41.000ï¿½ï¿½ and It's still comming (my family spend the time opening the envelopes and I spend my time finding "newsgroups"). This is getting serious!!!
At the end, it really paid the US$6ï¿½ï¿½ and six stamps investment. I sure spent more on lotto!!!
Let me explain how it works, and most of all, the reason why it works so well. Make sure to print a copy of this article RIGHT NOW so you can get all the information needed.
It's a very simple 3 step process:
STEP Nï¿½1: Get six pieces of paper and write this down on everyone: "PLEASE INCLUDE ME IN YOUR ADDRESS LIST OR E-MAIL." Now get six US$1ï¿½ï¿½ bills. Then, fold the papers and put the one dollar bill in each so it won't be seen through the envelope. It'll be better if you cover the bill with a dark color paper so it won't be stolen. At the end you'll have six sealed envelopes with six one dollar bills enclolsed. By doing this you're creating a "service" which makes it ABSOLUTELY LEGAL!!!
Send the envelopes to the following addresses:

1. Oscar Javier Rodrï¿½guez z
CR 31 # 45 - 23 barrio el triunfo, Villavicencio Colombia

2. Jorge Balcï¿½zar
Convento San Juan de los Lagos Nï¿½ 36, Jardines de Santa Mï¿½nica, C.P. 54050, Tlalnepantla, Estado de Mexico, Mï¿½XICO

3. Marco Vinicio Gramajo Leal
2a. Avenida 4-66 Zona 1, Mazatenango Suchitepequez, Guatemala, Centro Amï¿½rica.

4. Ricardo Portillo Arteaga
Calle Gonzalo de Berceo Nï¿½ 52 piso 2ï¿½ letra B, codigo postal 26005, Logroï¿½o - La Rioja, Espaï¿½a.

5. Javier Piï¿½eros Barreto
Carrera 72 No 62 f 33 sur, manzana 2 entrada 3 apto 102, Urbanizaciï¿½n Calabria, Bogota Colombia,

6. JAVIER DARIO ARENAS
Apartado postal : 243003
ADPOSTAL: Palmira - Valle Del Cauca - Colombia
Email: adarting@hotmail.com o darting@latimail.com

STEP2: Remove name #1 of the top of the list and move the other names one number up (#6 becomes #5 and so on), add your name and address as #6. REMEMBER, YOU MUST REMOVE #1 NOT #6, MODIFY THE NUMBER ON THE REMAINING NAMES AND ADD YOUR NAME AND ADDRESS TO THE LIST AS #6.

STEP3: Change all those things you consider to be changed in this article, but try to keep it as close to the original as possible. Now put your article on at least 200 "newsgroups" (there are more than 24.000 groups). Just search in google.com by the keyword "newsgroups" and you'll find more than 56.000 items. You just need 200, but the more you put the article on line, the more money you'll get!!
These are instructions to get into the "Newusgroups":
Nï¿½1 Since you must have your own article, there's no need to write it all over again. Just select the whole text and use the "copy" function from the "edit" menu.
Nï¿½2 Create a "notepad" file and "paste" the text, also using this function from the "edit" menu. Now you have the text as a notepad file and you can add your name and address as #6.
Nï¿½3 Save the text as a .txt file. This will make It easier for you to make chages on the text whenever you want.
FOR THOSE WHO USE NETSCAPE
Nï¿½4 In the Netscape browser go to "window" and select "netscapeNews". Then, select "options" from the menu and then selct "show all Newsgroups" so you can get the list of all the "Newsgroups" in the server. Click on any of the newsgroups, and then click on "TO NEWS", it should appear at the top on the left. This will lead you to the messages box.
Nï¿½5 Fill in that space. That will be the title everyone will see when visiting any group.
Nï¿½6 Copy your article and paste it there. Go back to the Newsgroup and "TO NEWS" and you'll be creating and pasting inside the program or "posting".
Nï¿½7 Click on "send" AND YOU'RE DONE!..CONGRATULATIONS!!
TO THOSE WHO USE INTERNET EXPLORER
Step Nï¿½4 Go to Newsgroups and select "Post an article".
Step Nï¿½5 Load the article
Step Nï¿½6 Repeat step Nï¿½6 for the Netscape users.
Step Nï¿½7 Press "Post"
THAT'S ALL! All you have to do is search for different Newsgroups. After a few loads, It'll take like 30 seconds to put the article in each newsgroup!
Eventually you might want to get a P.O Box ‘cause you're gonna get a great ammount of envelopes. You can also use a nickname as long as the address is correct. MAKE SURE THAT ALL THE ADDRESSES ARE CORRECT.
Now, let's check the numbers:
Supose I only get 5 answers out of 200 sent messages (which is a really low example), then I made US$5ï¿½ï¿½ with my name as #6 on the list. Now, if everyone who sent me US$1ï¿½ï¿½ contact a minimum of 200 Newsgroups too, all of them with my name as #5 on the list, and just five answer to the 5 original messages, I'll get US$25ï¿½ï¿½. This 25 persons put my name as #4 on a minimum of 200 Newsgroups getting just 5 answers I'd be makin another US$125ï¿½ï¿½. Then, 125 persons put my name as #3 on a minimum of 200 Newsgroups, again getting just 5 answers, I'd be getting another US$625ï¿½ï¿½ and so on!! With my name as #2 I'll get US$3.125ï¿½ï¿½, and as #1, US$15.625!!!

Now, as I said before, getting only 5 answers is extreeme, the real average of answers is 20 to 30, so DO THE MATH!!!
Once your name is out of the list, get the last ad on the newsgroup and send the US$6ï¿½ï¿½ to the names listed and put yours as #6 and start all over!!
Just remember: Thousands of people all around the world surf the Internet every day reading the article just like you and me! So I think many of them wont see a problem on investing US$6ï¿½ï¿½ to see if it really works. I know that some will think, "what if no one answers?" No way!!! What are the chances that will happen, when there are millions of honest persons (like us) who need to pay bills, who are looking for financial independence and who are willing to give it a shot.
You can also do this by getting at least 200 e-mails. With this system, the probbability of success is 5% to 15%. Eather way you do it, always remember to be honest and I promaise you It will work.
Just make sure to print this article NOW. Try to keep a list to track all those who sent you money. Keep checking the newsgroups so you can see if everyone is playing fair. REMEMER, HONESTY ES THE BEST WAY TO GET WHAT YOU WANT. I've heard of people who sent the message with their names on the list but without sending the money and they hardly recieved any money back.
TIME IS IMPORTANT! Don't wait more than seven days from the moment you see this article! Let's follow the rules so we can all win! Don't forget to mention this extra money on your tax declaration. THANK YOU AND GOOD LUCK!

Ken- consider that these are a high "Q" device (narrow bandwidth)
and, that they are a tuned loop (the ends of the two rods form a
CAPACITOR-- and the plates of a capacitor increase capacitance, the
closer they get! The higher the capacitance, the lower the frequency.
The antenna , itself , is an inductor, and that INDUCTANCE doesnt
change.
"Tis that simple-- Jim NN7K

>What is an example of using a stub on a ham antenna, its real purpose
>and how it does it?

Hi, A stub used on a ham antenna is generally a "matching" stub. It is a section of transmission line that exhibits capacitive or inductive reactance depending on the length and termination of the line. (open or short). Used to transform a complex antenna impedance to the feedline characteristic impedance. It may or not require other devices to realize a successful impedance transformation.
I don't know what an R5 is, on beams, a hairpin match (stub) is often used for impedance matching.

A similar product was used to paint the Hindenburg and it is now believed by many (but not all) that it was this that destroyed it. The film of the flames looks 'wrong' for a hydrogen fire. A sample of the skin, which had been saved for many years, was subjected to a spark test and burned with great enthusiasm.

The Euro seems to be the best bet at the moment. But wait for deregulation of the Yuan. And what Platinum prices are
you using? When I checked many years ago when someone touted Platinum as a good hedge bet, it ran some 15-20% higher
per ounce than Gold. Then Gold went up while Platinum stagnated, and the per ounce price was close to the same for a
while. I admit, not being a Gold Bug, I haven't followed it in a number of years, however.

1115. Tuner smoke!

Newsgroup: rec.radio.amateur.antenna
Date: 2005-01-17 02:29:30 UTC
From: Ken Bessler <kg0wx@NOSPAMyahoo.com>
Message-ID: <eqFGd.18256$ph.4264@okepread01>
Source record: 83354

I have 2 HF antennas - a 160/80 trap dipole (coax traps)
fed with 60' of coax directly and a shortened Van Gordon
"All Bander", cut to 7.165 mhz, fed in the following order:

Tuner
20' RG58 coax leading outside
9 turns rg 58 on a 5-1/4" air form
50' 450 ohm ladder line
Antenna

I tried tuning the 160 antenna on 18mhz and the tuner was
fighting me all the way. Would I do better to try and only
use the 40m antenna with the tuner from 30-10m because
of the ladder line? I'm guessing that I'd do better on 60m
with the larger antenna but I'm not sure. 95% of my HF
operating is below 7.300mhz, where the tuner is in bypass
mode.

Facts:

Rig FT-857D
Power 100w
Tuner: MFJ-941C
The big antenna resonantes at 1.875 & 3.890 mhz.....

For DX or anything beyond a few hundred miles, you shouldn't make your vertical taller than about 5/8 wavelength. At greater heights, the radiation at low angles decreases and the radiation at high angles increases. So taller isn't always better. You probably won't be able to construct a single vertical that's reasonably efficient on the lower frequency bands without being too long for low angle radiation on the higher frequency bands, unless you include some sort of trap(s) to limit the length of the radiating portion on the higher bands.

2 or 3% silver is added to tin-lead solder to prevent leaching of gold or silver terminations from certain surface mount components (and the terminal strips in very old Tektronix scopes). These components are often used for hybrid circuits, but solder-coated terminations seem a lot more common for components intended for PCB use. I haven't seen a leaching problem with the solder-coated terminations using ordinary tin-lead solder.

Is there some other advantage of a 2 or 3% silver addition?

It's inevitable that every time this topic comes up, someone confuses the 2 or 3% silver-loaded tin-lead solder with the hard solders known as "silver solder". They're entirely different things. The 2 or 3% silver-loaded tin-lead solder is a soft solder, very similar in use and properties to ordinary tin-lead solder. The "silver solders" used for brazing stainless steel and other materials are hard solders, with a much higher melting point and very different properties.

A fair number of surface-mount components (caps and resistors) use
silvered terminations. Some of them have an anti-leaching coating
over the silver (nickel, or solder with or without silver), others
don't. There's also silver plating on some of the RF connectors I
use. I'm probably being excessively cautious, but figure that it
can't hurt to use a silver-loaded solder and it might save me one or
two failures over time.

It is also 'unlike' in that the link between smoking and lung cancer is
a 100% proven fact (well known since the 1950s) whereas the link between
cellphones and brain tumours is at best tenuous.

Surprisingly, people are suing tobacco companies on the grounds that
'they didn't know' that smoking was bad for you. I suspect that these
are the same type of people who want to ban phone masts, but not the
phones themselves, of course, ie pretty thick!

That is only a time displacement. In 1900, after hundreds (thousands?)
of years of tobacco use, the link between smoking and lung cancer was
"at best tenuous".

Check out www.communication-concepts.com . They have ap notes and kits of parts based on Motorola designs. There are bipolar amplifiers, down to about 20 W. FETs generally require at least 28 or 48 VDC, and you will have trouble finding a design for less than about 100W output, although I have seen some low power amps (in QST) based on IRF series switching transistors.

If this is for VHF or UHF, you can go to www.rfparts.com , and find complete Mitsubishi and Toshiba modules.

1131. MFJ vs SGC automatic antenna tuners??

Newsgroup: rec.radio.amateur.antenna
Date: 2005-01-17 15:06:12 UTC
From: Spam <spamcollector@sympatico.ca>
Message-ID: <pan.2005.01.17.15.06.11.322900@sympatico.ca>
Source record: 83273

I have used an SGC 230 automatic antenna tuner in a maritime mobile application.

It is basically a PI-network tuner. However the capacitors on the input or output side of the PI-network need not be utilized, so it self configures as:

1. PI-network

2. L-network with an input capacitor for matching low Z loads.

3. L-network with an output capacitor for matching high Z loads.

The switched input capacitor values are 100, 200, 400, 800, 1620, and 3200 pf.

The switched output capacitor values are 25, 50, 100, 200, and 400 pf.

The switched inductor values are .25, .50, 1, 2, 4, 8, 16 and 32 uh.

The capacitors are switched in and out in parallel. The inductors are switched in and out in series.

The input C can assume values from 100 to 6320 pf in steps of 100 pf. The output C can assume values from 25 to 775 pf in steps of 25 pf. L can assume values from .25 to 63.75 in steps of .25 uh.

The ARRL antenna tuner analyser software calculates the impedance ranges such a tuner can match.

When the 230 tuned up, it worked well. When it didn't, often tuning up on an alternate frequency and then tuning up on the desired frequency would solve the problem. Sometimes, but not always, pactor would drive the unit crazy. It would launch a tune up sequence for each packet. SGC has a mod that locks the tuned position disabling repeat tune ups. Our 230 was too old for the mod.

Unfortunately the 230 died when it was stored in tropical Australia for 3 years. Water condensed inside the sealed unit, totally filling it and corroding the circuit board. Three monsoon seasons can do that. Furuno RADAR domes have flexible plastic breather tubes designed to prevent condensation. I wish SGC had done that too or filled them with pressurized nitrogen or taken some other measure to prevent condensation.

Live and learn. I am looking for a replacement tuner.

The MFJ website states they are L-network tuners. Are they C input or C output L's?

What are the impedance ranges an MFJ tuner can match?

Are the MFJ units designed as a hefty tuner for use at the antenna or a light weight used to flatten the SWR at the transmitter?

Since they are not weather proofed, I suspect they are designed for use at the transmitter. Ditto for LDG tuners.

How would an MFJ tuner stack up against a SGC 230 or ICOM AT-120 tuner?

Tnx

"Capacoitance and capacitive reactance are two separate things."

Yes. But, they are inextricably related by:

Capacitive reactance = 1 / 2 pi f C
where pi = approx. 3.1416,
f = frequency in Hertz,
Capacitance is in Farads, and
capacitive reactance is in Ohms.

Mike,
A 'long wire' (really a 'random wire', but that's being
picky) can have an input impedance all over the place depending
on the frequency of use. Most receivers just aren't too
picky about it, so try it and see what you get in reception.
You can always experiment with antenna length or matching
systems to improve things, but in most cases, they aren't
going to make a lot of difference.

> --

To put you in a good-enough ball-park, the input impedance of a vertical wire, or an inverted-L antenna, is R + jX, where -

R = Square(24 * L / Lambda) ohms.

X = - 550 / Tangent(Angle) ohms,

and where

L = overall length of the wire in metres.

Lambda = free-space wavelength in metres.

Angle = 2 * Pi * L / Lambda, in radians.

Or alternatively,

Angle = 360 * L / Lambda, in degrees.

For a thick lattice mast, change 550 to 350.

If you know what it is, add the ground electrode resistance to R. Otherwise make a guess.

The foregoing good-enough approximations apply to overall wire lengths or heights of 3/8 wavelengths or shorter.

Note that when L / Lambda passes through 1/4-wavelength, the reactance X passes through zero and changes from negative (capacitative) to positive (inductive). And R passes through 36 ohms as is common knowledge.

About the only practical use of the above pair of equations is if you intend to follow by designing your own tuner, coil and capacitor values. Or checking that a commercial tuner has an adequate range of operation. For this a small computer program is needed unless you have hours to spend on doing the unavoidable calculations.

But the real value of such simple equations lies in their ability to precisely and very succinctly describe how antennas WORK. Far, far better than thousands of vague words, spread over years, from agumentative, disruptive, albeit well-intentioned do-gooders.

I know its a cheap make but the build quality is very good to excellent and it matches in with my AOR AR5000 and SDU5600 and works well....

were i need the help is the only weak point with this ATU is the two small switches. one of has fell apart inside. i have just got two good quality replacements. when i removed the top cover i found one wire off. this wire is about one and a half inches long it is connected to the tuning 2 variable capacitor this wire can only have come off the coupler off switch.....

i am looking for somebody who has this very model (MIZUHO KX-2 Sky Coupler) i want to ask could you remove the top cover and take a photo of the internal parts mainly the front controls including the two variable capacitors so i can inspect the photo,s and find out were this wire connects to....

i have searched the internet but can not find much information on this model....does anybody have or know were i can obtain a copy of the wiring diagram for the KX-2.......

Hi Greg,

These, and other questions, are answered at:
http://www.mfjenterprises.com/man/pdf/MFJ-991.pdf

At a minimum:
"256 values of capacitance and 256 values of inductance are
available. With the inductance switched
between the input and output side, this provides a total of
131,072 L/C tuning combinations. The nominal
tuning ranges are 0 to 3900 pF and 0 to 24 ï¿½H."

It is a well know fact that RF modulated with naff TV (East Enders, Big
Brother etc) is rendered safe and has no adverse effects (unless you watch
the programmes).

For those with limited technical knowledge of EM radiation (eg at a level
where they believe in heat bands) the above is intended as humour.

Three to Six feet from closest tips. Further is better, but not often necessary. This depends on if they remain in tune, or if you can re-obtain a tune.

A "roof mounted 440 and a 2 meter" WHAT?

Antennas I suppose -- but the volume of OT posts here does not
preclude something else.

What kind of antennas? Vertical, horizontal, loop, yagi,
co-linear, fixed, rotated, common-mast, side-by-side, one
above the other?

The better questions _always_ get the better answers.

Separate transmitters? How much power? The answer is different for
two 500w repeaters than it is for a dual-band 5w HT.

Thanks, a web search was educational. Although one or two sources show only a single melting/solidifying temperature of 179 degrees C for 62Sn/36Pb/2Ag solder, others show a 10 degree C pasty range, with solid and liquid temperatures of 179 and 189 degrees respectively. This range is a bit wider than for, say, 60/40 solder which has an 8 degree range. This would be a disadvantage (probably a minor one) to using the silver-loaded solder.

I found two different sets of data for strength:

Tensile PSI Shear PSI
63/37 7500 6200
32/36/2 7000 7540

and

Tensile PSI Shear PSI
63/37 7600 5400
32/36/2 8600 6600

So it does appear that the silver-loaded solder has higher shear strength, and might have greater or less tensile strength, than unloaded solder. Despite the different numbers, both sources agree that the shear strength increase is about 22%. I wouldn't call that a "very LARGE amount" of difference, but that's certainly a matter of opinion.

Perhaps some people will find that the considerably greater expense, reduced availability, and non-eutectic behavior of silver-loaded solder is worth the modest increase (my opinion of 22% greater) in shear strength. But I doubt that many will. I keep a small quantity on hand for soldering SMD parts which have silver or gold terminations, but am satisfied with 63/37 for everything else.

Dear Rick:
I missed your response of some days ago.
Now I understand the actual issue.
When I feel like it, I have a manually adjustable vacuum variable capacitor that I use to shunt feed a tall tower for 160 meters. The "tap" is such that the real part of the impedance is about 50 ohms and the capacitor cancels the inductive part of the impedance. I use an AEA CIA right at the capacitor to find the right adjustment and then connect the Heliax.

In your case, a partner at the base might make small adjustments while you radio back what you wish for him/her to do next.

Do let us all know the solution you find. Good luck. 73 Mac N8TT

I<ve been reading up a bit more (and I see what you mean...I<m not sure the missus would be keen on a real long wire in the backyard!) and I think I<ll play around with some DIY antenna tuners to see whats what. I was mainly concerned with signal loss due to load mismatch if I use coax to get the signal into the basement for the wire.
thanks again
Mike

This is for a dual mode radio with two antenna outputs. (ALinco dr 590)
I am thinking of using a yagi for 440 and some type of omnidirectional
for 2 meters like a 1/4 ground plane.

Great pictures. Too bad it exhaust heat to the left side. My
AL-80X exhaust heat out the rear. I would consider 80B if it
could be modified to exhaust heat on the right side.

Dear (I really mean it) Roy,

For my (unstated) benefit, you semi-seriously describe yourself as an 'old wife'.

Now, I have NEVER described anyone as being an 'old wife'. I am too polite. Although, I must admit, I do occasionly infer that such people do exist. They are not objectionable

If you think the cap fits, then wear it. (Old English proverb.) But you don't!

But for the benefit of anyone mildly interested, who may be unfamiliar with the goings-on on this newsgroup, YOU are the VERY last person who I would remotely associate with being an 'old wife'.

Just keep yourself familiar with 'arithmetic' and 'maths' will look after itself. ;o)

History, Arithmetic and Elementary Statistics are the most neglected subjects in English primary schools. They are easy and simple enough and occupy little time. But what can be expected from ill-educated teachers? I suspect the same applies in the USA.

I understand school teachers in the USA wear bullet-proof jackets. But, in general, I am restricted to the BBC and the largely US-controlled unruly English newspapers which concentrate on swasticas and the royal family, nudes, the sexual habits of film-stars, cat-walk celebraties and overpaid Manchester United football players. After all, everybody has a right to make a living of some sort!

Just another advert from Reg, G4FGQ

RB wrote:
"What is the likely Z range such a circuit might match?"

A coil in parallel with a variable capacitor can be tuned to offset reactance in the antenna. At resonance, a parallel circuit with a high Q has a very high impedance.

Edmund A. Laport in "Radio Antenna Engineering" writes on page 310: "Experiment has shown that the correct termination of a long-wire in this manner (low-characteristic impedance wire to maximize antenna current) requires a complex impedance and not solely a resistance. The terminal impedance is of the type R+jX. The inductive reactance can be obtained from the extension wire by making it longer than one-quarter wavelength. This means that the correct resistance, obtained by experiment, must also be located in the correct place along the wire, and that the correct location is more than one-quarter wavelength from the end of the wire. The resistance has an order of magnitude of 400 to 600 ohms in many cases, and 500 ohms is suggested as a starting place for trials when the antenna consists of a single wire. The reactance values required usually should be between j150 and j250 ohms, so that with thin wire, the extension wire whould be somewhere around 105 degrees long."

Best regards, Richard Harrison, KB5WZI

For selected definitions of "OK".
The UV radiation will eventually turn it to dust. Here at 7,700',
that occurs in about 3 years. Painting it may delay that problem.

For material taken from that site, the spelling is generally an
indicator of the quality of reporting:
>... considerable gain and this is consentrated almost parallel to ground ...
with sentence structure providing an inverse relation (note, the
original was 43 words long).

More spelling indicators:
>hense the name SLIM JIM.

And from the editor (sic):
>Editor's note: ... What have you got to loose?

It is simply a J-Pole, with what the medicos would call "a redundant
prepuce."

I don't know how well it will work on 440 but I built a 220 quagi about 20 years ago and put at 40 feet. It is still up and working. The boom was not PVC but some of the grey electrical conduit. That is suspose to be more UV resistant than PVC pipe.

"If the roof is made of non-conductor material such as wood or composition shingle, the antenna will not "see" it and the height above ground is the important thing."

Yes, at least one of the important things. Antenna elevation is important to lower the elevation angle of propagation. It`s also possible there are noise generators within the house which make reception more difficult when a conductive roof isn`t present to shield the roof mounted antenna from noise. A small separation can make a large difference in noise source "signal" strength. A one wavelength separation can lower noise source received level by 22 dB. Then 6 dB more every time the distance doubles after the initial 22 dB loss. It`s best to have receiving antennas located well away from noise sources.

Best regards, Richard Harrison, KB5WZI

I use an MFJ-994 in a Maritime Fixed-Land. It is advertised to handle 12-800 ohms. It has its quirks too, but is easy to shift from line-flattening every transmit to memory-only.

Back when I was doing microwave stripline-on-sapphire, the solder of choice was a mixture of tin and indium (and perhaps a bit of bismuth) that we called tindium. It melted well below the boiling point of water. (No, it wasn't Wood's metal.)

Leaving aside the spelling, the real nonsense is "considerable gain". It looks very like a J-pole, and has a very similar radiation pattern and gain.

1186. Coax Switch To Switch One Antenna Lead Between Several HF Transceivers ?

Newsgroup: rec.radio.amateur.antenna
Date: 2005-01-19 07:32:19 UTC
From: Gary
Message-ID: <5l2su0pe4heegft8g945p0jkrjt6176439@4ax.com>
Source record: 83224

Can anyone recommend a good coax switch that I could use to switch between 2 or more HF transcievers (100 W) to one antenna lead ? I've got a friend that uses an old Heathkit coax switch to do as I've described to switch between a TS-2000 a Corsair II and a TS-830 but I'd like to make sure there's sufficient isolation or that the unused inputs are grounded before I go and fry a front end.

Thanks in advance.

So it is basically a j pole? I guess it would perform like one? I am going back and forth and cant decide what to do for two meters. It looked like a fun project. I j=have some 1/2 inch conduit and thought about welding it togther like that just to see how it worked. And installing some stainless steel bolts in the ends to "tune" it.

The problem is figuring out how to mount it. It says it has to be insulated and at least 20 inches away from metal.

> MADE FROM AND WHERE DO YOU GET THEM?

The end feedpoint impedance of a 5/8WL vertical is about
150 - j600 ohms. The coil is used as a loading coil to cancel
that capacitive reactance and is usually tapped and fed at
the 50 ohm point. Construction details for a 2m 5/8WL mobile
antenna are contained in "The ARRL Antenna Book" which is
an excellent first book on the subject of antennas.

Here's what EZNEC sez about a 1/4WL Vs a 5/8WL vertical.

1/4WL 5/8WL
-0.14 dBi at 26 deg. TOA 0.1 dBi at 26 deg.
-0.75 dBi at 17 deg. 1.4 dBi at 17 deg. TOA

Whether that 2 dB advantage at 17 deg. is worth all that
extra effort depends upon what kind of operating you do.
It can make a difference for CW DX.

Many many many years ago, one of my kid buddies built a Heathkit DX-35 transmitter. He couldn't get it to work, sold it to me.

The solder joints were absolutely TERRIBLE. Sooo, I plugged in my Weller gun and remelted one. A puff of acrid smoke erupted. He had used "Liquid Solder". Room temperature.

The good news: he had left all the component leads full-length, so I just clipped everything out, replaced the toob sockets and tiepoints and reinstalled the parts with real solder. It worked, I sold it.

Is that the same as a 1/4 ground plane vs 5/8 ground plane? It is just
I have seen 5/8 antennas advertised with gain.
On another topic, Would it be bad to use RG6 for the antenna and radio?

1197. Re: PHOTOS - inside Ameritron AL-80B 1KW amp

Mike wrote:
"I was mainly concerned with signal loss due to load mismatch if I use coax to get the signal into the basement for the wire."

A versatile tuner allows a match between antenna and radio under most conditions. It does not prevent an unshielded and imbalanced line from picking up noise on the path to the radio. Coax may avoid noise pickup.

Autotransformers at each end of the coax can give high-impedance match at the antenna and at the radio. Such transformers are used to match Beverage Antennas to coax.. See the "ARRL Antenna Book" or ON4UN`s "Low-Band DXing" for ferrite-winding details.

An air-core transformer at each end of the coax can step up / down the impedance too. Suppose you want to match 450 ohms to 50 ohms. The impedance ratio is 9 to 1. The turns ratio is 3 to 1.

The reactance of the primary may ne chosen as about 10 times the 450 ohms or 550 ohms of the antenna. About 500 microhenries (0.5 mhy) would work. My ARRL L/C/F Calculator shows the number of turns per inch, wire size, coil diameter, and coil length needed to make the coil.. There`s nothing critical about it. Its inductance was an arbitrary choice.

The coils are tapped up about 1/3 of the turns from the cold (grounded) end of the coil, for the coax connection. The full coil is used across the antenna and across the receiver input.

If you have no noise, a single wire connecting your receiver to the antenna will likely grab more signal and lose less of it on its way to the receiver.

I`ve used the transformers on each end of the low-impedance line (twisted pair)) to the receiver. This system was part of a 1938 GE "V-Doublet" antenna kit. It was a quiet all-band signal grabber.

Best regards, Richarrd Harrison, KB5WZI

Hi John

No, because my late wife made me take the eyehook back out, resharpen HER meat cleaver and sterilize it in boiling water.

Next time I'll buy my own meat cleaver and have a stainless steel tube welded to the side of it, hi hi....

FWIW: It was the 10 inch long 5 inch deep cleaver, not counting the handle. I think I would also have a flat steel plate welded to the top so it doesn't tear up the rubber mallet so bad too.

>>FWIW: It was the 10 inch long 5 inch deep cleaver, not counting the
>>handle. I think I would also have a flat steel plate welded to the
>>top so it doesn't tear up the rubber mallet so bad too.

I'm the nutter that bought and used a cheap electric chainsaw to bury my radials. It was exceptionally easy to use. Simply start at the antenna and drag the thing backwards. After that, I tucked in the radials with my hands. I won't do that part again, I'll use some sort of tool to push it in. Hundreds of feet of radial laying can wear the skin off your hands.

The major effect on the chainsaw was to dull the chain, as you might expect. THere was some mud in it also. The saw is out of commission because I was an idiot and lost one of the parts when I cleaned it. But under normal circumstances, no damage aside from the chain.

But when I get the thing back together, and in the spring, I will lay some more radials as an experiment, and likely post pix of the operation - along with the required warnings to never ever ever do that sort of thing - on our website

THIS IS REAL...TAKE YOUR TIME AND READ THIS.....NOBODY IS SCAMMING YOU
THE 5 MINUTES IT WILL TAKE YOU TO READ THIS WILL CHANGE YOUR FUTURE!

I'm sure you've read these letters asking you to send $1 to six different addresses. Putting your home address or mailing address on the internet can be risky, but through PayPal all you have to provide is your email address. It's safe and easy. Just go to WWW.PAYPAL.COM and set up your FREE account! No credit card is needed. I am not a gullible person and have never trusted things like this, but I gave it a try. Hey it's only $6. I figured at least 6 people would respond out of the millions of people that use the internet. You should give it a try too! You have nothing to lose, and thousands to gain! Read on for the letter that I found (of course, I added my PayPal e-mail on #6)...

HOW TO TURN $6 INTO $6,000+!!! THIS REALLY CAN MAKE YOU EASY MONEY!!!

IT WORKS!!! BUT YOU HAVE TO FOLLOW IT TO THE LETTER FOR IT TO WORK!!!!

A little while back, I was browsing through newsgroups, just like you are now and came across an article similar to this that said you could make thousands of dollars within weeks with only an initial investment of $6.00! So I thought, "Yeah, right, this must be some kind of scam" but like most of us, I was curious, so I kept reading. Anyway, it said that you send $1.00 though PayPal to each of the emails stated in the article. You then place your own email address in the bottom of the list at #6, and post the article in at least 200 news groups. (There are thousands) No catch. That was it. So after thinking it over, and talking to few people first, I thought about trying it. I figured what have I got to lose except $6.00, right? Like most of us I was a little skeptical and a little worried about the legal aspects of it. It follows the same regulations as the "mailed chain letters, which according to the U.S. Post Office (1-800-725-2161) is indeed legal! Then I invested the measly $6.00. Well GUESS WHAT!!? Within 7 days, I started getting money in my PayPal account! I was shocked! I figured it would end soon, but the money just kept coming in. In my first week, I made about $20.00. By the end second week I had made a total over

$1,200.00!!! In the third week I had over $10,000.00 and it's still

growing. This is now my fourth week and I have made a total of just over $36,000.00 and it's still coming in rapidly. It's Certainly worth $6.00. I have spent more than that on the lottery!! Let me tell you how this works and most importantly, why it works? Also, make sure you print a copy of this article now, so that you can get the information off of it as you need it.

$$

REQUIREMENTS: You must have a confirmed PayPal account. If you do not have a PayPal account you can go to www.paypal.com and follow the instructions to set up a free account. In order to place the initial $6 into your account, you will have to confirm your bank account with PayPal (which may take a few days). PayPal is 100% secure and is used my millions of people world wide. Confirming a www.paypal.com account simply means (1) PayPal will first ask you to confirm the email you used to sign up your PayPal account by sending you an email with a link for you to click to that email. As soon as you click that link your email is confirmed. (2) PayPal will then make two small deposits into your bank account if you set up your PayPal account with a checking or savings bank account. Or PayPal will make two small deposits to your credit card if you set up your PayPal account with your credit card. Then after a few days (it takes up to a few days for these deposits to appear in your bank account or on your credit card statement) then after a few days you go back to the www.paypal.com website and sign in. Then you click where it says this account is not yet confirmed. A screen will pop up that gives you 2 boxes to fill in. You then enter the numbers of the 2 small deposit amounts (two separate 2 digit numbers) that were deposited to your bank account or credit card. Now you have a working and confirmed PayPal account and can receive payments.

$$

[STEP 1]
Send, though PayPal, $1.00 to each email on the below list. Make the subject of the payment "Email List" and in the comments, write "PLEASE PUT ME ON YOUR EMAIL LIST." What you are doing is creating a service by this - and best of all you are not giving your address to anyone you do not know. THIS IS ABSOLUTELY LEGAL!! YOU ARE CREATING A SERVICE. Here are the latest PayPal e-mails on the e-mail lists:
#1) bigmicrosoft @ yahoo. com

#2) mr_skunky29 @ yahoo. com

#3) bmedsker @ cablespeed. com

#4) honesteyez @ yahoo. com

#5) spontaniuz @ msn. com

#6) dholla @ hotmail. com

www.paypal.com

Subject of Payment: ***Email List***

Comments: ***PLEASE PUT ME ON YOUR EMAIL LIST***

[STEP 2]
Now take the #1) email off the list that you see above, move the other addresses up one (6 becomes 5 & 5 becomes 4, etc) the put YOUR email address (the one used in your PayPal account) as #6) on the list. **MAKE SURE THE EMAIL YOU SUPPLY IS EXACTLY AS IT APPEARS IN YOUR PAYPAL ACCOUNT**

[STEP 3]
Change anything you need to, but try to keep this article as close to original as possible. Now, post your amended article to at least 200 newsgroups, message boards, etc. (I think there are close to 32,000 groups) All you need is 200, but remember, the more you post, the more money you make - as well as everyone else on the list! In this situation your job is to let as many people see this letter as

possible. So they will make you and me reach!!!! You can even start

posting the moment your email is confirmed. Payments will still appear in your PayPal account even while your bank account is being confirmed.

$$

DIRECTIONS ON HOW TO POST TO NEWSGROUPS/MESSAGE BOARDS.

[Step 1]
You do not need to re-type this entire letter to do your own posting. Simply put your CURSOR at the beginning of this letter and drag your CURSOR to the bottom of this document, and select 'copy' from the edit menu. This will copy the entire letter into your computer's temporary memory.

[Step 2]
Open a blank Notepad file and place your cursor at the top of the blank page. From the 'Edit' menu select 'Paste'. This will paste a copy of the letter into notepad so that you can add your email to the list.

[Step 3]
Save your new Notepad file as a .txt file. If you want to do your postings in different sittings, you'll always have this file to go back to.

[Step 4]
Use Netscape or Internet Explorer and try searching for various newsgroups, on-line forums, message boards, bulletin boards, chat sites, discussions, discussion groups, online communities, etc. EXAMPLE: go to any search engine like yahoo.com, google.com, altavista.com, excite.com, then search with subjects like "millionaire message board" or "money making message board" or "opportunity message board" or "money making discussions" or "business bulletin board" or "money making forum" etc. You will find thousands and thousands of message boards. Click them one by one

then you will find the option to post a new message.

[Step 5]
Visit these message boards and post this article as a new message by highlighting the text of this letter and selecting 'Paste' from the 'Edit' menu. Fill in the Subject, this will be the header that everyone sees as they scroll thru the list of postings in a particular group, click the post message button. You're done with your first one! Congratulations! THAT'S IT!! All you have to do is jump to different newsgroups and post away. After you get the hang of it, it will take about 30 seconds for each newsgroup! **REMEMBER, THE MORE NEWSGROUPS AND/OR MESSAGE BOARDS YOU POST IN, THE MORE MONEY YOU WILL MAKE!! BUT YOU HAVE TO POST A MINIMUM OF 200** That's it! You will begin receiving money within days! **JUST MAKE SURE THE EMAIL YOU SUPPLY IS EXACTLY AS IT APPEARS ON PAYPAL.**
Have fun!

*CASH*CASH*CASH*

Posted By: B (205.188.197.157)
Date: 01/02/05

Turn $6.00 into $42,000...read this to find out how!!! READING THIS COULD CHANGE YOUR LIFE! I found this on a bulletin board and decided to try it. A little while back, I was browsing through newsgroups, just like you are now, and came across an article similar to this that said you could make thousands of cash within weeks with only an initial investment of $6.00! So I thought, "Yeah right, this must be a scam", but like most of us, I was curious, so I kept reading. Anyway, it said that you send $1.00 to each of the 6 names and address stated in the article. You then place your own name and address in the bottom of the list at #6, and post the article in at least 200 newsgroups. (There are thousands) No catch, that was it. So after thinking it over, and talking to a few people first, I thought about trying it. I figured: "what have I got to lose except 6 stamps and $6.00, right?" Then I invested the measly $6.00. Well GUESS WHAT!!... within 7 days, I started getting cash in the mail! I was shocked! I figured it would end soon, but the cash just kept coming in. In my first week, I made about $25.00. By the end of the second week I had made a total of over $1,000.00! In the third week I had over $10,000.00 and it's still growing. This is now my fourth week and I have made a total of just over $42,000.00 and it's still coming in rapidly. It's certainly worth $6.00, and 6 stamps, I have spent more than that on the lottery!! Let me tell you how this works and most importantly, why it works....Also, make sure you print a copy of this article NOW, so you can get the information off of it as you need it. I promise you that if you follow the directions exactly, that you will start making more cash than you thought possible by doing something so easy! Suggestion: Read this entire message carefully! (print it out or download it.) Follow the simple directions and watch the cash come in! It's easy. It's legal. And, your investment is only $6.00 (Plus postage) IMPORTANT: This is not a rip-off; it is not indecent; it is not illegal; and it is virtually no risk - it really works!!!! If all of the following instructions are adhered to, you will receive extraordinary dividends. PLEASE NOTE: Please follow these directions EXACTLY, and $50,000 or more can be yours in 20 to 60 days. This program remains successful because of the honesty and integrity of the participants. Please continue its success by carefully adhering to the instructions. You will now become part of the Mail Order business. In this business your product is not solid and tangible, it's a service. You are in the business of developing Mailing Lists. Many large corporations are happy

to pay big bucks for quality lists. However, the cash made from the mailing lists is secondary to the income which is made from people like you and me asking to be included in that list. Here are the 4 easy steps to success: STEP 1: Get 6 separate pieces of paper and write the following on each piece of paper "PLEASE PUT ME ON YOUR MAILING LIST." Now get 6 US $1.00 bills and place ONE inside EACH of the 6 pieces of paper so the bill will not be seen through the envelope (to prevent thievery). Next, place one paper in each of the 6 envelopes and seal them. You should now have 6 sealed envelopes, each with a piece of paper stating the above phrase, your name and address, and a $1.00 bill. What you are doing is creating a service. THIS IS ABSOLUTELY LEGAL! You are requesting a legitimate service and you are paying for it! Like most of us I was a little skeptical and a little worried about the legal aspects of it all. So I checked it out with the U.S. Post Office (1-800-725-2161) and they confirmed that it is indeed legal! Mail the 6 envelopes to the following addresses:

1) Nathan Gilreath 6049 Porter Ave. East Lansing, MI 48823

2) Beth Collins 1012 Woodbine Ave., Toronto, Ontario M4C 4C1

3) Melody McKinley 8 Huntingdon Drive Dartmouth, Nova Scotia B2V 1w1

4) C. Witt 12 Pine ST. Attleboro, MA 02703

5) Ben Ervin 1281 Cadillac Dr. Hamilton, OH 45013

6) D J Kelly 661 powell st apt # 3 Brooklyn Ny 11212

STEP 2: Now take the #1 name off the list that you see above, move the other names up (6 becomes 5, 5 becomes 4, etc...) and add YOUR Name as number 6 on the list. STEP 3: Change anything you need to, but try to keep this article as close to original as possible. Now, post your amended article to at least 200 newsgroups. (I think there are close to 24,000 groups) All you need is 200, but remember, the more you post, the more cash you make! This is perfectly legal! If you have any doubts, refer to Title 18 Sec. 1302 & 1341 of the Postal lottery laws. Keep a copy of these steps for yourself and, whenever you need cash, you can use it again, and again. PLEASE REMEMBER that this program remains successful because of the honesty and integrity of the participants and by their carefully adhering to the directions. Look at it this way. If you are of integrity, the program will continue and the cash that so many others have received will come your way. NOTE: You may want to retain every name and address sent to you, either on a computer or hard copy and keep the notes people send you. This VERIFIES that you are truly providing a service. (Also, it might be a good idea to wrap the $1 bill in dark paper to reduce the risk of mail theft.) So, as each post is downloaded and the directions carefully followed, six members will be reimbursed for their participation as a List Developer with one dollar each. Your name will move up the list geometrically so that when your name reaches the #1 position you will be receiving thousands of cash in CASH!!! What an opportunity for only

$6.00 ($1.00 for each of the first six people listed above) Send it now, add your own name to the list and you're in business! ---DIRECTIONS ----- FOR HOW TO POST TO NEWSGROUPS---------- Step 1) You do not need to re-type this entire letter to do your own posting. Simply put your cursor at the beginning of this letter and drag your cursor to the bottom of this document, and select 'copy' from the edit menu. This will copy the entire letter into the computer's memory. Step 2) Open a blank 'notepad' file and place your cursor at the top of the blank page. From the 'edit' menu select 'paste'. This will paste a copy of the letter into notepad so that you can add your name to the list. Step 3) Save your new notepad file as a .txt file. If you want to do your postings in different settings, you'll always have this file to go back to. Step 4) Use Netscape or Internet explorer and try searching for various newsgroups (on-line forums, message boards, chat sites, discussions.) Step 5) Visit these message boards and post this article as a new message by highlighting the text of this letter and selecting paste from the edit menu. Fill in the Subject, this will be the header that everyone sees as they scroll through the list of postings in a particular group, click the post message button. You're done with your first one! Congratulations...THAT'S IT! All you have to do is jump to different newsgroups and post away, after you get the hang of it, it will take about 30 seconds for each newsgroup! **REMEMBER, THE MORE NEWSGROUPS YOU POST IN, THE MORE Cash YOU WILL MAKE!! BUT YOU HAVE TO POST A MINIMUM OF 200** That's it! You will begin receiving cash from around the world within days! You may eventually want to rent a P.O.Box due to the large amount of mail you will receive. If you wish to stay anonymous, you can invent a name to use, as long as the postman will deliver it. **JUST MAKE SURE ALL THE ADDRESSES ARE CORRECT.** Now the WHY part: Out of 200 postings, say I receive only 5 replies (a very low example). So then I made $5.00 with my name at #6 on the letter. Now, each of the 5 persons who just sent me $1.00 make the MINIMUM 200 postings, each with my name at #5 and only 5 persons respond to each of the original 5, that is another $25.00 for me, now those 25 each make 200 MINIMUM posts with my name at #4 and only 5 replies each, I will bring in an additional $125.00! Now, those 125 persons turn around and post the MINIMUM 200 with my name at #3 and only receive 5 replies each, I will make an additional $626.00! OK, now here is the fun part, each of those 625 persons post a MINIMUM 200 letters with my name at #2 and they each only receive 5 replies, that just made me $3,125.00!!! Those 3,125 persons will all deliver this message to 200 newsgroups with my name at #1 and if still 5 persons per 200 newsgroups react I will receive $15,625.00! With an original investment of only $6.00! AMAZING! When your name is no longer on the list, you just take the latest posting in the newsgroups, and send out another $6.00 to names on the list, putting your name at number 6 again. And start posting again. The thing to remember is: do you realize that thousands of people all over the world are joining the internet and reading these articles everyday?, JUST LIKE YOU are now!! So, can you afford $6.00 and see if it really works?? I think so... People have said, "what if the plan is played out and no one sends you the cash? So what! What are

the chances of that happening when there are tons of new honest users and new honest people who are joining the internet and newsgroups everyday and are willing to give it a try? Estimates are at 20,000 to 50,000 new users, every day, with thousands of those joining the actual internet. Remember, play FAIRLY and HONESTLY and this will really work.

stryped@hotmail.com wrote:
> Is that the same as a 1/4 ground plane vs 5/8 ground plane?

Yep.

> It is just I have seen 5/8 antennas advertised with gain.

They have a slight amount of gain IAOI they have a good ground plane.
The additional gain of a well designed 5/8WL vertical is, IMO, only
important for HF CW DX and QRP digital work.

> On another topic, Would it be bad to use RG6 for the antenna and radio?

"Bad" is relative. RG6 is 75 ohms. When I was in high school, RG6 &
RG11 were very popular. If a center-fed dipole has a feedpoint
impedance of 73 ohms, then 75 ohm coax results in a very low SWR
on the feedline. The mismatch, is this case, is at the source
and is not anything to worry about. Of course, your SWR meter,
calibrated for 50 ohms, will not display the correct SWR on the
75 ohm coax. In the '50's, if our transmitter's pi-net output
would "load", our system was working just fine. Most of us didn't
even own an SWR meter back then.

There's an edger tool that looks like a hoe but the hoe is
in the same plane as the handle, like a conventional hoe had
been straightened out. It's in between a hoe and a shovel.
One stands on it, wiggles it side-to-side, and has a grove
to put a wire into.

If my swr meter wont work with 75 ohm cable, should I use rg58 thsn if
I cant find rg8?

How do you get 22dB down for one wavelength and 6 more for each doubling?
tnx

You could probably recalibrate your 50 ohm SWR meter to
75 ohms. Or if all you are using it for is to make your
transmitter happy, leave it calibrated for 50 ohms. In
the latter case, you are not measuring SWR. When a 50
ohm SWR meter indicates 1:1, it is looking into 50 ohms
which is what the transmitter wants to see.

By the way, I bought a 2 meter/220/440 mhz swr/watt meter that reads
radiated/reflective power. Is this a good meter to set swr? Are these
hard to use?

I found some rg8/u and it is kind of expensive but the concensous seems
to be to use that if I want accuracy.

Easy to use, not so easy to understand.

> I found some rg8/u and it is kind of expensive but the concensous seems

Re the grey vs orange/white stuff (In VK at least)

The grey electrical conduit has graphite (I think) added and therefore
has some conductivity.

What I am getting at is that with a design using (say) white material
there will be slight dimension differences when using the grey stuff.
Apparently it isnt good to use it for a colinear etc design where the
radiating elemnt is inside the pipe.

Cheers Bob VK2YQA

Stryped wrote:
"---I bought a 2 meter/220/440 mhz, swr/wattmeter that reads radiated/reflected power."

When you have forward power but no reflected power, you have a matched load. SWR with a matched load is 1:1. For other power ratios, there are charts, slide rules and a formula to convert a power ratio to an equivalent SWR.

SWR is one measure of the reflection coefficient. If you have a directional wattmeter, you don`t need an SWR meter.

Best regards, Richard Harrison, KB5WZI

Well, I just got rg 8 cable about 20 feet for free! The thing about it it has two pl259 connectors on it. I need to have one end free so i can wire up the slim jim or j pole I build this weekend. I really do not eant to cut the cable as I would like to use it when I put the permanent station up. See any way around this?

Can I use copper house wire 12/ 2 or so to connect to the points on the j pole then bring them to a so connector Then screw the rg8 pl connector into that? Will this through off the swr? What ohms is 12/2 wire?

He also gave me a short cable with two pl 259 connectors to connect between my radio and the swr meter. It was a guy at a motorola dealer. This cable is pretty thin and not rg8 but he said it was 50 ohms.
I plan on hooking the 20 feet from the swr to the antenna.

Hi Bob

I had made a stand up tool that would cut the groove, bury the wire,
and close the hole back up, just by pushing it across the ground.

The cutting blade looked like a giant sized pizza cutter, behind it
was like a very narrow pulley that rolled the wire from it's spool
into the ground, and behind that were two wheels spaced about 1/2 inch
apart. If your familiar with how a plow or corn planter looks, it
looked just about like that, only I used two wheelbarrow handles to
make the manhandled part of the unit.

But it didn't work!

The reasons it didn't work were simple.
Sod density and moisture in the ground dictated how many concrete
blocks had to be stacked on top of the unit to provide enough weight
to cut through to the required depth.
With that many concrete blocks stacked up, you were not going to move
it easily. No problem, add two more wheels for stability and a towbar
to hook it to the riding lawn mower.
Tree and bush roots were the next problem. It would jump over them,
leaving the wire way to shallow in those areas.
Pulling it by the lawn mower meant you couldn't get close to the
fences or obstructions at the end of the run.

Solution:
Back to the meat cleaver and mallet!
Cheap to buy, easy to rig, and very fast.
But mainly, with NO mess to clean up afterwards.

TTUL
Gary

Lots of J-Pole plans show a coax socket soldered directly
to the J-Pole stub.

Richard,

It should be a fun experiment.

The ideal power transfer for isotropic radiators in free space at one wavelength separation is given by 1 / ((4 * pi)^2) = 0.00633 or -22 dB.

The specific number, 22 dB, comes with some specific conditions.

Such as:

* Isotropic radiators, i.e., no gain.

* Free space, no modification of fields by the earth or a roof.

* The antennas are in the far-field regions of each other. This usually means the antennas are small compared to the wavelength. (Automatic for the isotropic radiator.)

22 dB may be an convenient number to remember, but it is essentially meaningless for the question at hand.

73,
Gene
W4SZ

>connector into that?

Sure. One fairly common J-pole design uses an SO-239 socket which is mounted directly on one of the copper pipes at the feedpoint (use a brass screw or bolt, and then some plumber's solder). This creates the ground connection. Then, just run a short piece of copper wire from the center pin of the SO-239, across the space between the pipes, and solder it to the other pipe - this creates the "hot" side of the feed. The feedline with its PL-259 plug is screwed into the socket, and ends up sticking out to the side.

See http://www.tcars.org/elmer/jpole.html for one such design, complete with a parts and materials list, and look at http://www.alpharubicon.com/elect/jpolejaden.htm for another. One design screws the SO-239 directly to the pipe, the other makes a mounting bracket. Do whichever you prefer - when properly adjusted and tuned the two designs should have performance so close to identical that you cannot tell the difference.

> Will this through off the swr? What ohms is 12/2
>wire?

No matter what attachment method you use with a standard copper-pipe J-pole, you must "match" it by adjusting the positions at which the hot and grounded side of the coax are connected to the copper pipes. As a rule of thumb, moving the attachment points upwards along the pipe causes the feedline to "see" a higher impedance. You adjust the position until your connection is at a point where the impedance is 50 ohms, and you end up with an SWR of 1:1 or close to it.

The easiest way to get good results is to use a set of published plans in which the original designer has found the correct matching point, and then reproduce the antenna as exactly as you can.

Probably RG-58, and it should be fine for a short run to the SWR/power meter.

What if you are using a design plan exactly with the same diameter
material but with different material, say conduit instead of copper?

If you direct connect an so connector. How do you adjust both sides? I
mean once the ground is in place it is hard to adjust the "hot" side
unless you bend the wire alot.

1240. Re: ANother coax question and update!

>What if you are using a design plan exactly with the same diameter
>material but with different material, say conduit instead of copper?

I would expect that the tuning would not change appreciably. The antenna's losses might be higher, but likely not enough to be noticeable.

>If you direct connect an so connector. How do you adjust both sides? I
>mean once the ground is in place it is hard to adjust the "hot" side
>unless you bend the wire alot.

You experiment a lot.

Maybe you build a bunch of antennas with different attachment points, and measure them out. Or, maybe you cut one copper-pipe J-pole, don't actually solder the pipes together yet (just depend on a friction fit while tuning), drill a spiral pattern of holes or a line of holes in the pipe to which you can try screwing the SO-239, and try a bunch of positions until you find one which works best. You then rebuild the antenna with a new piece of pipe which is drilled for the socket in only one place.

Or, you build a mounting-and-grounding bracket arrangement which allows easy tuning... as is shown very clearly in one of the two sets of plans I referred you to in the post you're replying to.

Like I said, the easiest way to get a working antenna is to exactly reproduce a known-working example. If you want to vary the design, you'll need to experiment, cut-and-try, and be willing to make mistakes and learn from them.

It is just I have some conduit and I can weld it. I thought is would be
interesting. I was thinking of building one of those "slim jims' but

think the mounting might prove to be a problem.

I am wanting to build a j pole, an arrow antenna type open stub, and maybe a ground plane just to see if there is any difference in them using for simplex and repeater operation. I eventually want to build a yagi for 440 and compare it to the dual band open stub j pole like the arrow.

I am just so confused over this j pole. So many people have different opnions. One says it should never be grounded or touch a metal mast others say it does not matter. SOme say it should use a choke of some type others say it does not matter. It is confusing. What do you think on that? I guess my uneducated opinion is it should be insulated and a few turns of coax used as a choke but this is just that the people on that side of the argument seem to be more convincing and some have doen models on nec but I really do not know.

Gene Fuller wrote:
"The specific number, 22 dB comes with some specific conditions."

Yes, but when you are calculating the decline in field due to distance from the source, 22 dB is convenient as the reduction within the first wavelength. Every time the distance doubles after the first wavelength, the volts per meter are halved. The power per square meter is thus quartered (decreases by 6 dB).

Best regards, Richard Harrison, KB5WZI

>It is just I have some conduit and I can weld it. I thought is would be
>interesting.

Sure. No reason not to do this. You may find that there are, or are
not significant differences from a copper-pipe J-pole. The
finding-out is part of what's interesting, no?

> I was thinking of building one of those "slim jims' but
>think the mounting might prove to be a problem.

As others have pointed out, a classic J-pole and a Slim Jim are the
same basic sort of antenna. The Slim Jim simply has a double-section
radiator, shorted at the top. The behavior and performance of the two
will be very similar.

See http://www.cebik.com/jp1.html for a lengthy discussion of such
J-pole variants.

>I am just so confused over this j pole. So many people have different
>opnions. One says it should never be grounded or touch a metal mast
>others say it does not matter. SOme say it should use a choke of some
>type others say it does not matter. It is confusing. What do you think
>on that?

Here's my take on it. At www.cebik.com you can find out a bunch of
other info and discussion.

The classic copper-pipe J-pole is neither a fully-balanced design nor
a fully-nonbalanced design. The impedances "seen" by the two sides of
the feedline are similar, but not identical, and thus there are going
to be somewhat-different currents flowing on the two sides of the
matching arm.

Now, some people feel that a J-pole gives the best and most consistent
performance overall if you force it to act as much like a balanced
antennas as possible... you force the currents on the two sides of the
matching stub to be as equal as you can, and you eliminate the
pathways which would allow RF current to flow down to ground through
other paths (that is, through a grounded mast, and along the outside
of the feedline).

To implement this approach, you insulate the J-pole (or Slim Jim) from
ground, and you use some sort of balun or choke on the feedline to cut
off the outside-of-the-feedline radiation. Some people loop the coax
a few times to create a choke, some people run the coax down the
inside of the copper pipe, some people stick a few ferrite beads on
the outside of the coax, and some people use a half-wavelength 4:1

coaxial balun.

This approach, carefully implemented, *may* give you a J-pole or Slim Jim whose radiation pattern closely approximates that of a classic half-wave vertical dipole. You're keeping RF currents from flowing in any places which could cause radiation which disturbs the pattern. A J-pole or Slim Jim of this sort would tend to be insensitive to small variations in the length of the feedline, because the feedline is choked off and is presenting a high impedance.

So, this is the right and best approach? Not necessarily.

The opposite approach can also work very well... you just build a J-pole, stick it on a metal mast, run the feedline down to your transmitter without choking, and get on the air. There are many, many such J-poles in operation today, with very satisfied owners.

Such J-poles *may* end up with a nontrivial amount of RF flowing down the mast, or down the outside of the feedline. This may disturb the antenna's radiation pattern somewhat (making it less than ideally omnidirectional), or may cause the SWR seen by the transmitter to change somewhat if the feedline length is varied or if the mast is touched (both of these can change the outside-of-the-feedline RF impedance and currents).

However, these can very easily be small and insignificant factors in many installations. Radiation from the feedline and the mast might actually help an antenna's coverage more than it hurts, in certain circumstances... it might "bend" the antenna's pattern into a direction where the slight additional gain is helpful, at the expense of a gain loss in another direction where there doesn't happen to be anyone that the owner doesn't want to talk to. A shift in SWR due to mast or feedline RF-current effects can often be "tuned out" of the system just by moving the feedline attachment points a fraction of an inch... in a base-station application such an adjustment, once made, would probably not need to be re-done unless you start changing cables or moving the mast around.

So... an insulated-and-forcibly-balanced J-pole may well be a more theoretically-perfect antenna in some sense, but a grounded J-pole with no attention paid to balancing or choking could quite easily work just as well in any given installation.

My own copper-pipe J-pole uses a hybrid approach (well, that's the polite term... "it's schizophrenic" is equally valid). It's grounded to the mast, but the feedline is well choked (it runs inside the copper pipe and through a couple of ferrite beads therein, and there's a four-turn choke loop just outside the end of the pipe). Why did I do it this way? Why not?! It works fine, it's been working fine for close to three years, and if an insulated-and-perfectly-balanced version gave me a dB or two better gain uniformity I would very probably never notice the improvement.

Just BUILD SOMETHING, guy. Don't wait around until you figure out the
One True Way To Do It Right. There isn't one... or, rather, there are
at least a thousand.

Lots of good answers. - so I'll add another 1.5 cents worth.
The coil is at the bottom normally with enough windings (coils) to add the right amount of inductance that will help to make a 50-ohm source happy.

MADE FROM COPPER - usually.
YOU MAKEM' - if you want to have fun.

Arrl website has an antenna handbook - and several volumes of 'The antenna Compendium" that can give you many hours of fun winding coils, building antennas, making up matching sections - and all that good stuff.

One tool I found helpful in playing around with antennas and transmission line is an MFG 259 Antenna Analyzer. - and there are others out there, too.

Well, I bought one of them in 1959, and in the original configuration IIRC, it had 3 gamma matches, one for each band.
When HyGain supplied the replacement blue potted traps because all the black jobbies filled up with water, they changed
to a direct feed with a "Beta match" which is a hairpin of aluminum wire to mostly provide DC continuity between the
terminals. They recommend a 6 or 8 turn coil in the coax to act as a current mode Balun. I do not have the element
dimensions for the old style traps or the gamma matches. I've looked for it several times recently, and it eludes my
finding it.

BTW, mine has been in continuous use since 1960 with the blue traps. The center insulators on the driven element
failed, as most of HyGain's plastic tended to do, so I redesigned them to use some industrial grade fiberglass, and all
is well.

I get the idea, or I suppose if you're as absent minded as I am and
the unused inputs are grounded you could be transmitting into a dead
short. I think for me I'll just stick wih switching coax between the
two rigs, it sounds less expwnisive that way.

Thanks for the input.

Capacitors are added to match the feeder to the antenna.

What you describe as an, "antenna tuner" actually matches the
TX to the feeder.

(Slightly more than that, in reality, because what is on the feeder
at the TX end depends on what is connected to the feeder at the
antenna end. However, one thing that the device know traditionally
as the antenna tuner doesn't do, is to tune the antenna!)

If I build a j out of conduit and make it more like a "U" cutting the
long and short and crossbar at 45 degree angles so they can be welded
togther, how would I measire the length to cut each piece? Can I mount
the cross bar to the mast since I wont have a bottom "leg"?

1260. Alternate material j pole construction question.

Newsgroup: rec.radio.amateur.antenna
Date: 2005-01-21 13:33:37 UTC
From: stryped@hotmail.com
Message-ID: <1106314417.579450.69570@z14g2000cwz.googlegroups.com>
Source record: 83199

I am experimenting making a j pole out of 1/2 inch conduit. What I am thinking of doing is making it like a "u" in that each piece, the radiator, stub and shorting bar are cut at 45 degree angles and welded togther. I have the dimensions using the 1/2 inch copper. How do i measure each pieces "length"? I mean in the copper plan they use t fittings and measure the radiator length starting incide the t fitting where it is lower than the shorting bar.

My ides was to just measure the end of the angled piece where I cut it to the top, but not sure if this is right. What do you think?

Also, since an antenna constructed this way will not have an "extended leg" to mount to a mast, would it be acceptable to mount the shorted horizontal section to the mast? Will this cause problems?
Any help is appreciated. I hope to work on this tomorrow.

1261. Experience with Resonant Feedline Dipoles requested

Newsgroup: rec.radio.amateur.antenna
Date: 2005-01-21 13:58:37 UTC
From: TerraDactyl@shadowstorm.com
Message-ID: <41f1084d.30737538@127.0.0.1>
Source record: 83200

I've attempted to build several Resonant Feedline Dipoles for 10 meters, and so far they seem to be flaky at best. The first one I made out of about 25 feet of RG-8M coax and it came up with about a 1.5:1 SWR, but the rest had high SWRs. I may have used a ferrite core for the RF choke instead of the coiled coax on the first one, but I don't remember for sure. I tried to make another one out of some RG-8 foam with coiled coax for the choke, and it never would tune up. On two other occasions I tried making RFDs with RG-58 and coiled coax chokes, and the SWR was 1.8 on one of them and out of sight with the second one. Has anyone else managed to consistently make RFD dipoles with low SWRs, and if so what type of coax and choke were you using?

Thanks

-TD

Caps are cheaper than antenna tuners? One disadvantage
of shunt caps is that their reactance goes down as
frequency in increased thus requiring a separate cap
per band. I prefer a shunt coil whose reactance increases
with frequency so it can be left in place. It gives the
proper amount of parallel inductive reactance on 75m,
twice as much reactance on 40m, 4x on 20m, and 8x on 10m
thus having less effect as frequency is increased.

One other way to accomplish the above matching to 50 ohms
is to use a transformer, either a conventional one or a
transmission line transformer (UNUN).

However, an antenna tuner at the source makes the
transmission line into a tuned feeder. It tunes the
antenna *system* to achieve a Z0-match that re-directs
all the reflected energy back toward the antenna.

Given a 1/2WL resonant dipole, 1/2WL of ladder-line
is a tuned feeder. 3/8WL of ladder-line plus 1/4WL
provided by the antenna tuner results in a tuned
feeder system.

Except in the case where the feed point impedance of the
antenna is resistive and an exact match (rare, possibly
unlikely!) to the surge impedance of the feeder.

ie, for the concept of a tuned feeder, there has to be a
standing wave on it.

Michael Mannung wrote:
"What is the reason a capacitor is added to a shunt fed antenna?"

Shunt feeding a radiatir has advantages. It eliminates the base insulator. Shunt feed acts as a dingle-turn loop. Field of the loop magnetically induces voltage into the radiator. Attachment point on the radiator is picked to nearly match the resistive part of the radiator impedance to the Zo of the transmission line at the connection point. There is always an inductive reactance at this point which can be tuned out by using a variable capacitor connected in series with the shunt feed connection.

The capacitor is simple to adjust, cheap, and nearly lossless as compared with a coil.

I am assuming that you are talking about using EMT conduit.
It will rust pretty quickly and the welds will rust even sooner.
Why not use 1/2 inch copper plumping pipe?

Yes EMT conduit. I will paint it to keep it from rusting.

I have emt at my house and I can weld it. I dont have enough copper and
I have never soldered copper plus I would have to buy a bunch of
fittings.

Hey Don, with a QRZ.com birth date of "01 Nov 0001",
you must have known Jesus. :-)

Why don't you start with the Arrow Antenna design?
It's actually a Zepp design where the driven element
is 1/4WL and the parallel "grounded" element is 3/4WL.

1274. Balun Use/Need

Newsgroup: rec.radio.amateur.antenna
Date: 2005-01-21 18:06:42 UTC
From: Richard Fry <rfry@adams.net>
Message-ID: <35culkF4gtpqjU1@individual.net>
Source record: 83213

There is a general belief that a balun should be used where coax connects to the feedpoint of a 1/2-wave dipole (for example), to avoid RF current on the outer surface of the coax outer conductor -- which can affect antenna input match, radiation pattern etc.

But does even a perfect balun fully remove these effects? The outside of the outer conductor of the coax feedline still will be coupled into the received and/or radiated fields, even when there is no current flowing into the coax outer conductor via a metallic connection directly with the dipole itself.

As an illustration of this, consider the effect of a 1/2-wave dipole suspended near, and parallel to another 1/2-wave dipole. Only one dipole is driven. For simplicity of concept, let's say the active RF device (either a tx or rx) is a physically small unit built in to the center insulator of the driven dipole, e.g., no feedline. Standard equations, and NEC-2 analysis show that considerable interaction exists between the two dipoles. The input match of the driven dipole changes, and the radiation pattern of the simple dipole is strongly affected. Yet the only coupling between these two dipoles is by radiation.

So how important is the balun in the total RF system?

RF

There ia a 144 MHz Super-J in the "ARRL Antenna Book". It`s on page 16-24 of my 19th edition. Individual piece drawings and measurements are presented for novice builders.

The "Antenna Book" Maritime Antenna is "Super" because it is a collinear using (2) 1/2-wave sections, in phase, and end to end. For a simple J-pole, eliminate one 1/2-wave section and the 1/4-wave phase-inverting stub.

Stainless steel is used fotr the "Super J-pole", but rustable steel can be used if deesired.

There are two sources for common-mode current. One is
conduction. The other is induction. Since common-mode
currents are somewhat unpredictable, the best way to
ascertain if there is a problem is to measure the
current. A toroidal pickup slipped over the coax will
give one a relative reading and is super simple to
implement.

Hi OM,

What you fail to bring into this is the "degree" of coupling. The
transmission line being orthogonal is in the plane of the dipole's
null - hence zero conduction. It only supports conduction through
either direct connection (which the BalUn/Choke breaks) or loss of
symmetry (not falling in the plane of the dipole's null or the
environment distorting that electrical plane - an unbalanced dipole).

>As an illustration of this, consider the effect of a 1/2-wave dipole
>suspended near, and parallel to another 1/2-wave dipole. Only one dipole is
>driven.

This, again, reveals the nature of "degree" of coupling. That is, in
your scenario the second dipole MUST be parallel AND broadside. If it
were parallel and online, the coupling would be considerably (10 - 15
dB) less.

>So how important is the balun in the total RF system?

What is the "degree" of coupling?

No, it doesn't, for the reasons that Richard gave, and Cecil summarizes below.

The reasons why these currents can appear is because the antenna, the feedline layout and/or the environment is asymmetrical - and often it's all three.

How much unwanted feedline current you have will depend on the physical layout, how long the feedline is in wavelengths, and where and how it may be grounded at the shack end. That's what makes it unpredictable, as Cecil says below; so whether or not you need a balun will depend entirely on your particular situation.

>
>There are two sources for common-mode current. One is
>conduction. The other is induction.

The 'conduction' component of the current is launched onto the feedline where it connects to the antenna, and a good choke balun at the feedpoint can effectively knock it out. The balun at the feedpoint doesn't have to be perfect; only good enough to make sure that the conduction current doesn't dominate any more.

That leaves the 'induction' component of the current, which is due to asymmetrical electromagnetic coupling between the antenna and the feedline. Unless the feedline is much closer to one side of the antenna than the other, this induction component will generally be much smaller than the conduction component was (before you mostly removed it with a balun at the feedpoint).

If the remaining induction current is a problem, you may need to use additional chokes at various places along the feedline. Depending on the feedline length and the grounding arrangements, there will be current maxima and minima at various places along the feedline. The most effective place to put a choke is obviously at a maximum, where the current is trying to be large; the least effective place is at a minimum, where it's low anyhow.

The last traces of feedline current are very hard to kill completely. It's rather like trying to squeeze the air out of a long balloon - choke the current in one place, and a new maximum will try to pop up somewhere else. Even so, a few chokes in the right places - and always put the first one at the feedpoint - will almost definitely put you in control of the situation.

But how do you know how much current you've got, and where the current maxima are?

Here is a whole page about clip-on current meters, which have the advantage that you don't have to disconnect the cable to feed it through a toroid:
http://www.ifwtech.co.uk/g3sek/clip-on/clip-on.htm

The clip-on gadget is a bit more trouble to build, but you'll be very glad you did! With one of these, you can actually *see* how much RF current you've got, and where it is. Without it, you might as well be investigating RFI problems with your eyes shut.

Richard

I'd sure like to see radiation pattern from testing or modeling you do on
this "dipole pattern". I have been wondering about how the feed line can
be disassociated from effecting the dipole's radiation pattern.
I finally decided to make my feed for a 137MHz dipole by using two 50 ohm
coax cables to form a 100 ohm balanced line. That alowed me to locate the
balun at a place where its effectiveness is not important.

1287. Basic Question: How does an antenna tuner work?

Newsgroup: rec.radio.amateur.antenna
Date: 2005-01-21 20:10:03 UTC
From: Paul Hardwick <ask4@myemailaddress.com>
Message-ID: <vkdId.187589$48.46411@fe1.news.blueyonder.co.uk>
Source record: 83126

...its not as easy as that though. See, I know that it filters out the desired frequency, but I was wondering HOW its does it.

I understand that as the RF waves hit the antenna, they cause free electrons on the antenna to go up and down, and this electrical current (as movement of electrons causes) is then rectified and amplified (talking simply now), and pumped out to the speaker. For this example, I think it would be best to stick with a really simple radio, operating with an Amplitude Modulation.

I imagine the free electrons on the antenna to be very much like a bouy bouncing around on the sea - going up and down. If there was only one continuous sinusoidal wave hitting that electron, then it'll be going up and down quite simply. But then the voice and music we hear is modulated into that sine wave, so the electron is going up and down, plus "wibbling" about because of the modulated speech. Taking the bouy example again, I imagine a tuner very much like a telescope looking at the bouy, and the telescope bouncing up and down at the same rate. What I should see looking through the telescope is the bouy bouncing up and down slightly according the music and voice that has been modulated into it - the carrier wave has been cancelled out because the telescope and bouy are moving up and down at the same frequency.

This sounds all right, but if I then continue to take this analogy further, the bouy (or electron) is moving up and down to MANY frequencies. So even if I am bouncing up and down at the desired frequency, the chances of me seeing the bouy in the right place because of all the other frequency waves are probably nil.

Also, how does the tuner stay in phase with that broadcast, when there are no synchronisation going on?

To round up, the question is this: how can the tuner only select those electrons that are ONLY vibrating at the required frequency, when logic states that the electron must be bouncing around at the combined, additive effect of all RF waves hitting it!

Anyone care to have a go and answer?

Cheers.

Paul.

But the nulls of a dipole are off its ends. The t-line connects to the dipole center, where relative field normal to the longitudinal axis of the dipole is at a maximum.

Dear Paul,

It's elementary. Look up the Superposition Theorem. You will find that
in a linear system it is possible to single out any one (or more) of
the existing effects and treat it (them) individually. In other words,
if you restrict the bandwidth of the system so as to study the effects
of only one signal, then that is the only one you will see.

Hi OM,

It takes only a moment to visualize a dipole, frozen in time, where each arm supports the opposite charge. The continuum of forces between the two, in three-space, shows a distinct plane of response where a net-zero force is exhibited. This reference plane, a virtual ground, falls between the poles and is orthogonal.

A common artifice of erecting vertically polarized antennas above dipoles bears this out. The two are invisible to each other. It also allows for the use of towers to support beams, but also explains why guy wires which violate balance (do not fall within the plane) must be broken up as conductors. The towers have a smaller degree of coupling than do the guy wires that support them.

Even folded dipoles in commercial installations make use of this reference plane by providing a mounting point (180 degrees from the feed) to the support structure. No regard needs to be made for "shorting" out the loop at this point.

The null you speak of is exhibited in the far field - the utility of BalUn/Chokes are in the near field. The transmission line may lie within the reference plane, but its metallic connection to one of the poles necessarily violates the electrical balance. The BalUn/Choke isolates this connection.

Of the solutions presented in the ARRL Antenna Book for 2nd storey grounding...ha, ha! There are no solutions!

But that doesn't help me.

I live in an apartment - a set of rooms in a 100+ year old building, so you'd THINK they'd have copper/metal plumbing; but, no. It's been pvc'd. So no cold water pipe.

The ARRL cautions, and I concur, against dropping a long bit o' wire from the window to the ground - many issues, including having the ground wire function as a resonator, or, RF burns from touching th radio. Don't want those.

There's the MFJ "artificial" ground, but I don't see how that would work with the ATAS 100 I have - like having an antenna tuner for an antenna tuner.

Any thoughts?

thanks,
kc0olm

What does the ATAS 100 feed, and where is it? Just use complete
antennas.
Myself, I wouldn't worry about it. You don't need a ground in the
shack for rf purposes, as long as the antenna is not fed directly from
the
shack. IE: random wire fed from a tuner in the shack, etc..I haven't
used
an rf ground in the shack for years. I would not waste any money on an
MFJ "artificial ground". MK

Is this the little mobile whip antenna Yaesu makes for 40 thru 2
meters? It needs a ground -- the kind you'd have, attached to a car.
Otherwise, in your apartment, you might try attaching some 1/4 wave
radials to the grounding point for the device, for each band you want
to work. Without a ground, half the antenna system is missing.

> The null you speak of is exhibited in the far field -

The near-field boundary is located at about 2*(Ant Length)^2 / lambda, which for a 14 MHz, 1/2-wave dipole is ~32 feet away. The far-field radiation pattern shape is not well formed inside that boundary, but radiated fields are non-zero, nevertheless. A coax feedline that does not project on a radial normal to the dipole feedpoint will have current induced on its outer conductor by coupling to the dipole -- whether or not a balun is used.

i have the same antenna and rig, if your using it on a car as entended
, try adding a ground wire from antenna mount base to car chassis
w/good wire and also ground radio it's fickle about grounds

if your using it off a car i find you need at least 3 radials before
it will tune and be happy but each area is different perhaps you need
more

good luck

I need help understanding these different types of verticals.

What is the feedpoint Z of each of these?

I can't understand how a 5/8 can even work. It seems like it has to be
multiples of 1/4 wave for any antenna to work.
Why not a 7/8 wave antenna?

Why does a 5/8 wave antenna need a loading coil and a 1/4 wave antenna
doesn't?

Is there such a thing as a 1/2 wave whip ant. fed at the bottom?

Are there other sizes of whip antennas?

Hi Don

Don't let them get to you!

Both the Callbook and QRZ had me so messed up for most of my ham career that I never knew if I was coming or going.

After several invitations to join the QCWA, I was eventually turned down because of an error in the callbook, the ONLY source they use for verification.

At one time I held something like 4 or 5 callsigns, which is a major no no. The callbook had me listed under 2 different callsigns, neither of which were accurate.

One time, when I went to upgrade, the FCC obviously lost my valid callsign and refused the upgrade. Made me start over from scratch. Then after passing all the tests, one right after the other, and after my new call came, they finally found their error.
It was the retaking of all the tests so closely together that caused me to have so many callsigns appearing as valid.

The problems started with my very first callsign, it arrived with my address shown correctly but bore my Elmers name. Thus when the 1959 callbook came out it too was in error, even though the FCC corrected the problem and issued me a new certificate. For some reason, the callbook perpetuated this error in subsequent editions.
The FCC would not let me renew that callsign while I was out of the country away at school. So upon returning home from college I got a new callsign in 1972 that I never intended on changing. But the FCC lost it, that is why I had to retake all of my upgrades over again. Every callbook since has showed my Amateur Since date as being a different start date.

Speaking of the QCWA, I had sent them massive amounts of paperwork, copies of licenses and logbooks, signed affidavits from hams who new me, copies of newsletters and even school yearbooks and radio club affiliations and even copies of current logbooks showing the many errors being perpetuated concerning me.
They refused to consider any factual evidence of my being a ham, and relied solely on the erroneous callbook in their library.

So when they began inviting me to join again, I reminded them quite clearly that they turned me down flat in the past, nothing has changed, the callbooks are still in error. And I don't want to belong to a club that DON'T want me!

I also AM NOT a member of the ARRL, due to foulups they have made!
And other incidents between them and myself, which I won't bore you
with here, other than to say, they are a greedy money based
organization that looks out for themselves, NOT for the Hams they
claim to look out for.

You are confusing the RF waves with the electron carriers. The easiest
way to stop confusing waves with carriers is to stand on a cliff
looking out over the ocean. (Fitzgerald's Marine Reserve, just north
of Santa Cruz, CA, is an ideal place.) There are all sorts of waves
using the same water molecule carriers. There are big waves rolling
straight in and smaller waves rolling in at an angle. The waves
rolling in reflect off the beach and roll back out to sea. Each of
these waves maintains a separate identity even though they are using
the same individual water molecules as the wave carriers.

RF waves do the same thing - share individual quantum carriers for
any number of waves. All the waves are superposed on each individual
carrier, but each wave maintains its individual identity.

Note that water waves and RF waves are different kinds of waves but
they do share the above limited characteristic concerning carriers.

1320. Re: 5/8, 1/4 and 1/2 wave help?

Newsgroup: rec.radio.amateur.antenna
Date: 2005-01-22 17:12:16 UTC
From: Caveat Lector <CL@barahmas.com>
Message-ID: <QPvId.15761$ru.7000@fed1read07>
Source record: 83159

First off an antenna does not have to be resonant to work. There are many designs using non resonant antennas.
An example is a random wire using a tuner.
See URL:
http://www.qsl.net/ve3mcf/elecraft_reflect/Antennas_Non-Resonant.txt

For 1/4 to 5/8 wave antennas

Going from 1/4 wave to a half wave to a 5/8 wave vertical results (in each case) in a lower angle of radiation, thus 'gain"
See URL for a pictorial of this
http://www.wingsandwheels.com/page14.htm

Another at URL:
http://web.wt.net/~nm5k/acompari.htm

Be aware of what antenna gain means
Antenna gain is somewhat a misnomer, as "Ya can't get out more than ya put in". In reality no antenna has gain, only losses due to inefficiencies So what is meant by antenna "gain"? The gain spoken of has to do with shaping the antenna radiation pattern so that more energy is radiated along a given plane as compared to a reference antenna. In effect the radiation pattern is squished into a narrower directional beam. Squeeze a round toy balloon to visualize the effect.

Several reference antennas can be used, but the ones most often used are the dipole and an isotropic antenna. When using the dipole as a reference, the subjective value of zero dB gain (dBd) is assigned (except NMEA, National Marine Electronics Association, which assigns it a subjective value of 3 dB gain). The isotropic antenna is by theory an infinitely small sphere that radiates equally in all directions. By comparing a real antenna to this standard, a figure of merit can be expressed in dB, usually stated as dBi. That is, the gain of the real antenna over the isotropic reference. Since the real antenna does not radiate equally in all directions, some plane of directivity must be specified.

Every antenna, other than an isotropic will have gain in some direction at the expense of that in others. This gain of course, comes from not radiating power in all the other directions. And the beam width is measured at the minus 3 dB points (half power points) so the antenna "hears" and "talks" well beyond the beam width specification.

A Half wave vertical will have a lower radiation angle than a 1/4 wave and presents a very high impedance feed point. The feedpoint is a voltage maximum, has high impedance, and thus must use a critical matching network

to be fed with conventional coaxial cable. Such a network is often no more than an autotransformer with about a 2000 Ohm secondary and a tap at the 50 Ohm point. In any case, since the natural impedance of the end-fed half-wave is so high, it is not influenced by the presence or absence of ground.

A 5/8-wave antenna adds 1/8-wave to the length of the 1/2 wave radiator, which shifts the voltage-current relationship by 45 degrees and creates a low-impedance antenna. This is also easier to match to coaxial cable, since the match ratio is much smaller and the network used will be more efficient. 5/8 wavelength antennas are not resonant. The purpose of such an antenna design is to raise the current maximum higher up the antenna, thereby yielding a lower angle of radiation.

Normally a matching method is used, since the characteristic impedance of such an antenna is capacitive and the resistive component is greater than 50 ohms

A tapped coil is used to feed the antenna with coax, thereby canceling the capacitance and providing an impedance transformation to 50 ohms.

http://www.qsl.net/w4sat/five8th.htm

As you extend the wavelength above 5/8 (actually 3/4 lambda as I recall) the antenna begins to exhibit split lobes with some at relatively high radiation angles. So 5/8 is about the maximum practical wavelength for a vertical antenna.

For a quarter wave antenna, the feedpoint impedance might be around 32 Ohms (various factors enter into this), but many designs use drooping radials to achieve a 50 Ohm match.

The ARRL Antenna Handbook will elaborate on these designs.

> the dipole is at a maximum.

The orthogonal part is the important part. The radiation "sees"
the transmission line on edge and doesn't induct (much) energy
to it. The energy transferred from the antenna to the feedline
is a function of the cosine of the angle between them. If the
feedline is hanging down vertically from a horizontal dipole,
for common-mode purposes, the feedline is vertically polarized
and the antenna is horizontally polarized. It is when you bend
the feedline at some angle other than 90 degrees to the antenna
that the cosine of that angle becomes non-zero.

The Al of two toroids of the same material changes
with physical dimensions. The permeability is still
100, but the cross section area has changed so the
Al (uH/100T) changes in the formula.

OK for a horizontal antenna. Causes unwanted high-angle
radiation in a vertical.

> Why does a 5/8 wave antenna need a loading coil and a 1/4 wave antenna
> doesn't?

A 1/4WL vertical with a ground plane is resonant. A 5/8WL
vertical is not resonant and requires some sort of matching.

> Is there such a thing as a 1/2 wave whip ant. fed at the bottom?

J-Pole is a good example. The bottom 1/4WL of a J-Pole is
the matching section.

> Are there other sizes of whip antennas?

Any length of vertical whip up through 5/8WL will work well
if you can deliver the RF energy into the antenna. For
practical matching purposes, whips without internal loading
are usually limited to about 3/16 wavelength. I've used a
13 ft. whip, resonant on 17m, on 20m with an autotuner and
it worked well. On 40m, it was a good S-unit down from my
homemade bugcatcher.

1324. OK, now THIS is wierd.....

Newsgroup: rec.radio.amateur.antenna
Date: 2005-01-22 17:53:07 UTC
From: Ken Bessler <kg0wx@NOSPAMyahoo.com>
Message-ID: <8qwId.288$PB.70@okepread01>
Source record: 83163

My HF rig was damaged earlier this month. I replaced
it (Yaesu FT-840) with a new FT-857D and all is working
fine but I'm getting wierd results from my antennas.

I have 2 HF antennas - a coax fed 160/80 trap dipole (uses
3-1/2" dia coax traps) and a shortened Van Gorden
"All Bander".

On all three bands with the new rig I'm getting about 1/3rd
more bandwidth between the 2:1 SWR points. The SWR
meter hasn't changed and the feedlines and antennas are the
same - only the transciever has changed. Power is as before
- 100 watts.

What could be causing this? The only thing I could think of
is that my old rig was "dirty" and the harmonics were adding
to the SWR.

Hi OM,

This is arguable at best, and suitable newsgroup fodder for endless
speculation on the contributions of superposition and the combination
of direct and induced currents.

The classic study of Engineering reveals one principal:
The well defined problem contains its own solution.

The omission of the BalUn/Choke is not revealed as a solution to your
complaint above. It has already been disclosed by others on how the
further application of choking can resolve this crafted failure.
Their discussion and my own comprise a general solution that responds
to the necessary correlative:
What is the degree of coupling?

> I need help understanding these different types of verticals.
>
> What is the feedpoint Z of each of these?
==========

Feedpoint impedance is expressed in terms of R + jX. Both numbers are functions of frequency or wavelength. For a simple wire vertical less than 3/8 waves, with sufficient ballpark accuracy -

R = Square(24 * Height / Wavelength) ohms,

X = - 550 / Tangent(Angle) ohms, where -

Angle = 360 * Height / Wavelength) degrees.

==========
> I can't understand how a 5/8 can even work. It seems like it has to be
> multiples of 1/4 wave for any antenna to work.
> Why not a 7/8 wave antenna?
==========
Indeed, why not?

Any antenna WORKS quite satisfactorily REGARDLESS of how long it is. After all it is only a length of wire. Why should it work better merely because it is some special fraction of a wavelength?
>
==========
> Why does a 5/8 wave antenna need a loading coil and a 1/4 wave antenna
> doesn't?
==========

A 5/8ths antenna doesn't need a loading coil. It will work just as it is. But a loading coil is useful to tune-out the reactance of the input impedance and so provide a better match to a transmission line.

To assist in EXACT matching of a 1/4-wavelength antenna to a 50-ohm line a loading coil plus capacitor is needed. But you can nearly always do without either. With a 36-ohm line, if you can find one, there's a near-enough perfect match. But then you have to match to 50-ohms at the transmitter end so you get nowhere.

==========

> Is there such a thing as a 1/2 wave whip ant. fed at the bottom?
==========

Yes. There is. Why not? It's quite a normal thing to do. The matching and especially ground losses are exceptionally small.

==========

> Are there other sizes of whip antennas?

==========

Yes, any size you like. As long as you can find room in your back yard. They will ALL work quite efficiently. Unless, of course, they are extremely short in terms of the free-space wavelength. Say less than 1/100th wavelengths.

Very short antennas result in losses in the matching or tuning arrangements needed to match to the usual 50-ohm transmitter. Antennas are themselves inherently very high efficiency devices.

For values of R + jX, and other information such as loading components, download free programs from the following website. For clues, look under each program name in the list for a brief one-line description of a program's purpose.

Values of R + jX are usually of secondary importance. They are educational in that they provide information about antenna behaviour. They are practical only if it is the intention to design impedance matching networks or to check the operating range of commercial tuners.

You could try program ENDFEED first. Just put the horizontal length of an Inverted-L equal to zero and you are left with a vertical. But there are several other programs dealing with verticals directly and which values of R + jX appear in the output data alongside values of L and C of the tuning network.

Apart from the necessary nuts and bolts, you could dispense with half of the ARRL Handbooks! All for free! ;o)

As for radiation patterns of verticals, from zero up to a height of about 0.6 wavelengths, for amateur practical purposes they are all the same. Omni-directional. And in the vertical plane a couple of very broad adjacent hemispheres with a vertical null.

For an RF ground, the connection from transmitter/antenna tuner to a good ground should be a half wafelength long at the operating frequency. For more frequencies, add more half wave wires. But dont coil the wires. hi the height is less than about 0.1 wavelength, a straight wire connection is ok
Of course the usual rules for ground and connections apply.

I will email you* a NEC study showing two surface patterns from a 1/2-wave dipole; one with no feedline, and one having a conductor approaching within 2" of the center of the dipole and not attached to it, and not perpendicular to the longitudinal axis of the dipole.

The second pattern simulates a dipole fed by a sloping coax cable connected to the dipole feedpoint through a balun -- a fairly typical scenario for the coax feedline.

You can judge the affect for yourself.

*and any others wanting to see it

The only aspect of this that has not yet been presented adequately is
the artificial ground. I neither subscribe to nor recommend this, but
you should at least be aware of how it is intended to work.

The "artificial ground" has one end connected to your shack ground (in
your case the chassis of the transmitter or tuner will do nicely.

The other terminal of the "artificial ground" connects to a length of
wire that is just sufficient to connect to an earth rod driven into
the soil beneath the shack. The "artificial tuner" internals consist
of a series resonant circuit - a capacitor and a multiple tapped
inductor and an RF current detector. The "artificial ground" is tuned
for a maximum of RF current when your rig is transmitting. The
artificial ground with its length of wire from the rig chassis to the
earth rod makes up a series resonant circuit that is electrically an
integer multiple of a half wave. That presents the lowest possible RF
impedance between the chassis and the earth rod (as indicated by the
maximum of RF current in the artificial ground).

The effect of this will be to make the chassis of the rig "cool". It
will have no effect on the antenna tuner, but it will reduce the flow
of RF current through other devices in the shack via power cords.

I'm using a seperate SWR/Power meter. Both rigs, old and new,
had no internal tuner and used my MFJ-864. The FT-857D has
a SWR meter but it's not calibrated or even marked. So, I use a
seperate, dedicated & calibrated meter. I'm using a MFJ 941C
tuner but all my measurements have been with the tuner in bypass
mode, going direct to the antennas.

Dear Brian,

I was getting curious, because most people with the surname "Lay" do
come from England, but my family came from Germany, near Heidelberg,
in 1849.

Insofar as Web design, I would rather have nothing to do with the Web,
at all, but it's the only way to distribute my free software. I let my
grandson (Nick Zaffora) design my Web page. He's a college student and
really enjoys that sort of thing.

Dear Ken,

Then I'm going to suggest that which was my first thought - something
has probably been damaged by lightning, and it will probably require
that you take everything down and examine it inch by inch to find what
has happened. Be especially observent over the entire length of coax
for any sign of a burn.

I have had several strikes over the years that have caused varying
amounts of damage. Often, it is just a small burn through from the
inner conductor to the shield that leaves a lump of charred dielectric
at the point where it left the feed line and found some shorter path
to ground.

>Which is the best amateur-band automatic antenna tuner made, for use
>with a 160-meter inverted V with open wire feeders, to cover 160
>through 6 meters?

That's a good question C.J.. I doubt that you will find anyone here that has gotten their hands on all the automatic antenna tuners offered for sale, and done extensive testing on a 160 meter inverted vee on 160 to 6 meters.

>Also, is there much perceptible difference in performance, loss,
>signal strength, etc. between the best of the best and the ones that
>are only average in quality, assuming that both will properly tune the
>antenna?

Once again, who would have actual experience that could report on this? Seems like QST compared some auto tuners a while back, and there are product reviews by users on qsl.net. These are not all inclusive.
I have several automatic and manual tuners, both commercial and homebrew that I use in a variety of applications. The ones that work the best on an antenna like you describe are the manual ones with the roller inductors and HV variable caps. They will match a larger impedance range and handle power. The auto tuners are rated for 100 watts, (except for the HB one) and have a more limited matching range. I would make my decision based on the power handling capability of the tuner.
Another thing, Ham antenna tuners generally don't perform well above 15 meters, with a large antenna like you have. (stray L and C in the tuner). The radiation pattern is like a squashed spider. Be better off using a simple (and small) dipole on 17, 12, 10 and 6m.

Thanks, Bob but lightning was not in the area or even in the state.
My HF rig was physically damaged by a falling branch sweeping
past the window where some of my coax lines went out.

The coax cables I'm using were not affected nor were the antennas.
The ice storm had already broken the support ropes and those
antennas were on the ground when the branches came down.

I deliberatly incorporate a physical weak spot in the support ropes
so that the antenna will survive in case of a snag.

The 2:1 SWR range on 40m was 303 kc before. Now it's 465 kc.

well it would help if you give more info on your set up

are you using this mobile or base?

do you have the radio chases grounded to earth ground?

if base do you have ant radials? for each band u wish to use?

if mobile is the antenna base grounded to the car chases both at point
of attachment and a extra wire from the base to a chasess ground by
antenna base

it could be the antenna dosn't work or radio can't say for certain

is the antenna plugged directly into the radio?? if your going thur
anything like a tuner or filter etc etc , and if that blocks dc it
won't work

are you following the manual tuning directions exactly it's a bit
tricky at times

did you program the radio to use the ats100?

maybe some of these tips and info might help

let us know

good luck

Dear Ken,

If I may be permitted another guess. When you check the bandwidth on
the higher bands, you probably do not see as much of an increase from

the original characterstics. If so, then there is another mechanism that may have come into play. It does not take much of a droop on the ends of a lower frequency antenna, center supported antenna to give an effect of greater bandwidth. For example, I believe that you will generally find that an inverted vee antenna has a wider bandwidth than one that is near flat across the top (given that the center of each is at same height above ground. If your antennas are center supported and have a lower altitude at the ends than originally, that might account for it. Unfortunately, your description of your antennas sounds more like they are not center supported. As a general rule, as you surely know, anything that increases the losses in an antenna will manifest itself as greater bandwidth. That is the aspect that makes you really want to find the cause, because it means something is eating your watts.

With that I'm out of ideas.

Hate to be the bearer of bad tydeings, but the ATAS is a 40 meter-thru 450 MHz Screwdriver antenna-- PERIOD! It is NOT an antenna tuner, that function is in the rig that you use, or, as a company (haven't seen them advertize for some time) manufacturered a box that would supply voltage to your coax , to run the motor in the ATAS, allowing it to tune. Think the voltages (don't quote me!), were something like +12 volts to the center of coax to extend, and +8 volts (max) to retract the beast to tune it. this voltage in normally supplied by your Yaesu rig, but as stated, was company made a box supplying these voltages to the antenna for other rigs. Yaesu rigs that support these have a menu function for them- and control the SWR monitoring for this antenna. For any other rig, you will need to supply the appropriate voltages, while monitoring the swr, while tuneing it-and this antenna is now up to the ATAS 120, version, I believe- as info, Jim NN7K

Thanks for the ideas, Bob!

The antenna was never used on bands other than 40m before. Now,
it's my main antenna for use above 7mc. The only changes are the
addition of the tuner.

I know it's *not* the tuner because I've tested it with the tuner physically
out of line.

There are 2 other miniscule changes. Before the storm, I had trimmed
out the ends with 18g insulated speaker wire. Each leg had a butt splice
then about 2' of the stuff. Now the extra wire is standard 14g stranded
bare copper, soldered in place.

The feedline had 1 minor change, too. From the tuner I had 20' of rg58
going into a 9 turn, 5-1/4" dia air coil then 50' of 450 ohm ladder line.

The coil was wound on a CD-rom package with the turns held together
with superglue. The form was removed after the glue set up. Neat.

During the repairs, 1 turn of the coil broke loose and straightned out on
the side connected to the 20' of rg58 going indoors. The coil is 1 piece
still, just 1 turn less on the coax side.

The antenna is basically a flat dipole, supported by a wooden roof in the middle and rope at the ends. The ends droop maybe 2-3 feet.

I suppose the replacement of the end wire with heavier wire could help b/w but I wouldn't think that much.

I just checked my 160/80m dipole, where nothing changed so I don't think it's the radio or the tuner......

Thanks for scratching your brain for me!

Any one install or are using a Alfa Delta DX-A antenna.

Did you have to tune it?
Was it wide banded?
How was it on 160 Meters?

Thanks for any input.

Steve

Dear Ken,

Those things that you mention would not cause a change in bandwidth,
in my opinion.

Last suggestion:

If there were significant amounts of RF current on the outer surface
of the coax portion of the feed line, and if that has changes due to
the other changes, then there could possibly be unpredictable effects
on the SWR meter. They are not supposed to be sensitive to such
things, but in my shack any RF currents running around in the station
ground has always caused erroneous readings in the SWR meters. As a
last ditch experiment, I would try earthing the outer shield of the
coax to a good ground frame just before the coax comes into the shack.

Good Luck!

The original standard was 5 volt supplied by the GPS receiver,
HOWEVER this was changed to 3.3 volt with newer GPS model receivers.

NEWER antennas can handle both voltages (pre-amp inside).
IF you are looking at surplus antennas, unless they are proprietary to a
specific receiver, are likely 5 volt models.

> What you describe as an, "antenna tuner" actually matches the
> TX to the feeder.
>
==========

A misleading statement.

The TX design impedance is fixed, usually at 50 ohms.

So the antenna tuner matches the variable feeder input impedance to the TX design impedance.

But no doubt you will manage to squirm your way out of it. ;o)

Airy, you'll be telling us next the SWR meter reads the SWR on the
eedline - whereas it does nothing of the kind.

The confusingly, so-called SWR meter is merely a useful TLI. which Indicates
whether or not the Transmitter is correctly Loaded with its design
resistance. Usually but not necessarily 50 ohms.

It is realised this means re-editing all the handbooks which have appeared
during the last 50 years or so.

In that case what you need is a transfer switch, which someone makes, but I don't have a catalog number at hand. You
know, two inputs, two outputs, and you put the dummy load on the other output. What one should use for tuning up rigs
which need tuning anyway.

Because the would be stated as:

C is INVERSELY proportional to d

An other example, from the RF field, is the 'inverse square law'. If your
interpretation were correct it would be the "square law".

Not at all. As you (correctly) say, the name in the 'inverse square law'.
It too is a proportional ratio - in that case P in proportional to 1/(d^2).

N'est pas?

Preparing to install a Diamond VHF/UHF base vertical X6000A, and planning to paint it beforehand to a less visible color (here, dark green will be better than white).

Is there any issue with this (affecting RF performance)? Does the outer (fiberglass? plastic?) white jacket have any dielectric characteristic necessary for antenna operation that would be affected by paint? Any type of paint to avoid (I was planning Rust-Oleum textured dark green.) Tks,

Select the primer carefully. Rustoleum paints are designed to be laid over Rustoleum primers over steel. A good primer for steel might be a lousy primer for fiberglass. I'd check with a body shop which works on Corvettes for a recommendation on good primers for fiberglass. Rustoleum enamels over just about any decent primer will work.

Dave

I have tried to get some idea of the loss of dielectric stuff at RF by "cooking it" in the microwave for a short while to see if it gets hot. That may or may not be a method you could use to get more confidance about what paint to use.

Jerry

I've got a B@W that will do that. It's the B@W 594.
I've got wood board with many switches on it, side by side. Alpha delta
2 way,
B@W 6 way, B@W 3 way, and the B@W 594, which can be used to switch
between two
different rigs. I'm about a switching fool, considering my tuner also
has a
switch...:/ Also, many quite a few other stand alone
switches..."daiwa,etc,"
You can never have too many switches... MK

I thank you very much for the kind words.

But on more than a few occasions, I've found that I firmly believe something you have said with an air of confidence, even certainty, that is a belief only of "old wives". Therefore it's an inescapable conclusion that I am one.

Don't fret -- the title of "Reg's old wife" is one I wear with pride, if a modicum of bemusement.

1378. Swr meter in your base station

Newsgroup: rec.radio.amateur.antenna
Date: 2005-01-24 13:25:19 UTC
From: stryped@hotmail.com
Message-ID: <1106573119.064449.324240@z14g2000cwz.googlegroups.com>
Source record: 83117

I am just curious how many of you keep your swr meter hooked up in your base station? (I mean all the time, not just when you are tuning an antenna?)

1379. How does a "cross needle" swr work?

Newsgroup: rec.radio.amateur.antenna
Date: 2005-01-24 13:29:12 UTC
From: stryped@hotmail.com
Message-ID: <1106573352.171441.4060@f14g2000cwb.googlegroups.com>
Source record: 83118

I just bought one that measures forward and reflected power and at the bottom is the swr calculation.

Is the antenna's swr where the two needles meet?

Also the switch on it for 2 meters says "144 mhz" So I should tune my radio to this when tuning? What if I want my antenna tuned for 146 mhz.

It is an MFJ unit. Yes I did read the instructions but they left alot to be desired for a first timer.

1380. Re: Swr meter in your base station

yes, look behind where the needles cross and there should be a set of lines
calibrated in swr.

>

no, you set your radio for whatever frequency you want to operate on and
check the swr there. they label it 144mhz just to say what band it can
handle.

That's usually the case for MFJ cross-needle stuff. The
somewhat red vertical lines on my MFJ-949E indicate SWR
where the forward and reflected needles cross.

The whole idea is to tune your antenna so the Forward needle moves as
much as possible, while the Reverse needle moves as little as
possible, or not at all :-)

THe manual for your rig should tell you how much SWR it can safely
handle. A little doesn't hurt, but too much can harm the finals.

Here is one recommendation:

Antenna Painting Instructions

The following is courtesy Celwave This is what I received when I asked
them for a recommendation of what to use in refinishing my 18 year old
PD455

Celwave receives requests for advice about refinishing weathered antenna
radomes or changing the radome color for aesthetic
reasons. We do not take a position on any manufacturer's paint. However,
Sherwin-Williams seems to make a product, which
should be compatible with radomes and not interfere with the antenna's
electrical performance. The following suggestions are
not a substitute for detailed instructions and mix ratios provided by the
paint manufacturer.

RADOME MATERIAL (Standard Color)
CELWAVE PRODUCT LINE
1. Spun Epoxy Fiberglass (Blue)
Penetrator Antennas (AxR, BxR
Series)
2. Polyester Impregnated Fiberglass (White)
Stationmaster Antennas (PDxx Omni
Series.)
3. Polyester Impregnated Fiberglass (Grey)
FR CELlite Panel Antennas (AP18, 19
Series)
4. ASA (Grey)
FR CELlite Panel Antennas (AP90
Series)
5. AES/ABS (White or Grey)
US Panel Antennas (Other APxx
Models)
6. Gel Coated Fiberglass Tubing (White)

Marine Antennas (Cel-1, 3 etc.)

Notes:

FOR RADOME
MATERIAL
USE THIS FINISH
#1, #2, #3
Primer and Top Coat
#4, #5
Primer may be required ----

(Top Coat retention may be tested with adhesive tape after
paint dries)
#6
Requires Pre-Treat (Acid Etch) to remove gloss, then Primer
and Top Coat

SHERWIN-WILLIAMS PRODUCTS:

Etch
P60G2 "Wash Primer"
Primer
D61H75 "Polane 2.8 Plus Spray Fil"
Top Coat
Polane Type "HS 2.8 Plus Polyurethane"

SURFACE PREPARATION:

Removal of surface contamination is normally accomplished by using an
alcohol solvent, ethanol, propanol, isopropanol, or
butanol. A ten percent solution of methyl ethyl ketone in water can also be
used whenever stubborn oil or grease is
encountered.

APPLICATION PROCEDURES:

Painting to be done indoors, as the uncured product is sensitive to
moisture. Apply one coat of Polane 2.8 Plus Spray Fil
D61H75 Primer. It is designed to fill and/or hide profile and surface
imperfections on metal castings, structural foam, plastic and
wood. Apply one coat of Polane HS 2.8 Plus Polyurethane Enamel Monochromatic
Intermix Color System F63 Series.

Dave- why not use (it's NOT PAINT, per se), Fiberglass repair material available at most building suppiy companies, and also body restoreing kits for cars and boats? Have used this stuff to repair badly weather checked Green Hornet antennas, and the big advantage is that they also have color dyes available to "match" the original surfaces color ! This stuff also has the advantage that it is an epoxy base- not something that will fade, or flake off in a year or two! It also adds tensile strength if you are in a bad wx location. Biggest disadvantage is- once its on, its on (and that includes your clothes, skin, ect! Be careful applying it, and let it dry totally before trying to move/install it! as info, Jim NN7K

> proprietary to a specific receiver, are likely 5 volt models.

That's correct. I found out that the voltage range spec
is 5-26 volts.

1393. Dual Rhombic

Newsgroup: rec.radio.amateur.antenna
Date: 2005-01-25 14:38:27 UTC
From: Pierre Desjardins <pierred1@sympatico.ca>
Message-ID: <03mcv0d9vlip0llv09mfht36o53sokpfra@4ax.com>
Source record: 83032

Hi to all

I read somewhere that the dual rhombic could give a gain of almost 27 db using these dimension for 144,2 mHz:

L1- 29.5 ft, L2- 50.67 ft, X- 52.2 degrees, Y- 37.7 degrees, R1/2 660 ohms noninductive, Ht: 12.29 ft, Elevation angle: 7.5 degrees, Vertical beamwidth: 5.5 degrees and Horizontal beamwidth: 8.5 degrees.

Has anyone ever verified this? Here, using simulation with EZNEC+, I get about 15 dBi in free space and much lower on real ground. Am I missing something?

Thanks for your answers

No - it was a complete mistake.

First it was an optimistic estimate from pre-computer days. Then too
many different people each added another 6dB for ground gain.

When looking for a power supply for my Alinco dr-590, what type of power supply would I look for? The radio says 13.8 v dc but if I get a 12 volt power supply will it put out the same wattage at the radio?

Hi Don,

Do the math. You have the same load - less voltage. The power laws
describe this simply as Eï¿½/R.

However, it is very, very, very unlikely that you have 12.0 V of
anything as this is a "nominal" voltage, and almost never an actual
voltage. The 12 V label is derived from the common application of the
Lead-Acid Edison Battery. The cells of this battery develop 2.1 V
potential, and with their common combination into batteries of either
3 cells or 6 cells, those bring the total up to 6.3 V or 12.6 V. Many
here will recognize these values as common filament voltages for
tubes. So even here, common transformers that are either 6 or 12 V
specified, actually supply more voltage under load (because they were
originally filament power transformers).

The specification for 13.8 V is derived from the automotive electrical
system that was designed (with its voltage regulator and
generator/alternator) to supply a "float" voltage that would keep the
battery topped off while simultaneously carrying the load. Hence,
mobile applications are designed for this configuration and the source
should be robust enough to support the load.

Now, it seems to me you were using a deep discharge battery, or you
were planning to do so. This is a common application in the shack, I
have two batteries in parallel held up with a 20A trickle charge
(voltage adjusted to the optimum value). The charger (actually a
precision source from Acopian) is not large enough to supply my HF
rigs under full power out (my Drake TR-7 is rated well above 100W) but
the combination of batteries and charger manage quite well. Also, I
have connectored everything so that I can strip down, transport and
reconfigure for field day operations (sans charger).

12 VDC to 13.8 VDC are nominal voltages. Very few radios are sensitive
to variation of voltage as long as the power supply can supply the amps.
The Icom 706 series seem to be sensitive to .LT. 12 VDC. I can't speak
to the Alinco.
Generally the front of any given power supply will say 12 VDC but the
specs will indicate 13.8 VDC.
No, if you provide 12 VDC you will output a lower wattage regardless of
the capacity to provide adequate amperage.

Astron RS-20A, or a RS-20M if you want meters. That'll handle your 45
watt radio. It's a 12 volt power supply that is internally adjustable
up to and above 13.8 volts. Get the RS-35 if you plan on adding an HF
rig to your station. Astron is standard equipment on many radio desks.

I agree with Jim about Astron. Been using 'em for decades. Simple, robust design. Zero failures.
The voltage conundrum I believe derives from the necessary voltage to charge a 12 volt battery.
Gotta overcome that old internal resistance; Turns out to be about 13.8 volts.
I don't know of a "12V" ham rig that would care about the difference.
Get outside the manufacturer's specified range (RTFB) and you may not have a warranty.

Edmund A. Laport was Chief Engineer of RCA International Division Radio Corporaation of America, and is the author of "Radio Antenna Engineering".

On page 336 of "Radio Antenna Engineering" Ed gives the gain of a two-layer tiered rhombic as 14.7 dBd.

On page 528 of Arnold B. Bailey`s "TV and Other Receiving Antennas" is given the gain of a single-layer "horizontal" rhombic in free-space which has a dide length of about 3.7 wavelengths. It has a gain of about 14.5 dBd.

I`ve used Laport`s criteria in rhombic design and been satisfied.

Best regards, Richard Harrison, KB5WZI

So you are saying it wont matter?

I was wanting to use the marine battery I have but someone else posted a negative experience with the fumes ruining part of their house and their own health. It scared me a little.

I was looking at power supplies on ebay and some of them stated 12 volts (older ones) some said 13.8. That is why I asked.
I am still a little confused on what way I need to go.

1403. I made a lot of money doing this! Nothing to lose!

Newsgroup: rec.radio.amateur.antenna
Date: 2005-01-25 19:15:57 UTC
From: provgator@yahoo.com
Message-ID: <1106680557.610598.17120@c13g2000cwb.googlegroups.com>
Source record: 83042

I made a lot of money Try this!!! Nothing to lose
Make money quick while you are still young like me at 21!
MAKE EASY AND QUICK CASH MONEY by doing almost nothing (NO JOKE, NO SCAM, AND VERY LEGAL) Please read on! You will be very thankful you did! PLEASE READ LIFE CHANGING INFORMATION!! $6.00 to 42,000!! THIS IS AN EASY, HONEST, AND LEGAL WAY TO MAKE SOME QUICK CASH! WOW THIS REALLY WORKED! I CAN'T BELIEVE IT!! YOU WON'T EITHER! A while back, I was browsing these newsgroups, just like you are now, and came across an article similar to this that said you could make thousands of dollars within weeks with only an initial investment of $6.00 plus stamps! So I thought, "Yeah, right, this must be a scam!" But like most of us I was curious and kept reading. It said that if you send $1.00 to each of the 6 names and addresses listed in the article, you could make thousands in a very short period of time!
You then place your own name and address at the bottom of the list at #6, and post the article to at least 200 newsgroups. (There are about 32,000 of them out there and that's quite a large market pool). No catch, that was it. Even though the investment was a measly $6, I had three questions that needed to be answered before I could get involved in this sort of thing.
1. IS THIS REALLY LEGAL?? I called a lawyer first. The lawyer was a little skeptical that I would actually make any money but he said it WAS LEGAL if I wanted to try it. I told him it sounded a lot like a chain letter but the details of the system (SEE BELOW) actually made it a legitimate legal business.
2. IS IT OK WITH THE POST OFFICE OR IS IT MAIL FRAUD?.... I called them: 1-800-725-2161 and they confirmed THIS IS ABSOLUTELY LEGAL! (See Title18, h sections1302 NS 1341 of Postal Lottery Laws). This clarifies the program of collecting names and addresses for a mailing list.
3. IS IT MORAL? Well, everyone who sends me a buck has a good chance of getting A LOT of money ... a much better chance than buying a lottery ticket!!! So, having these questions answered, I invested EXACTLY $8.04... six $1.00 bills and six 34 cent postage stamps ... and boy am I glad I did!!! Within 7 days, I started getting money in the mail! I was shocked! I figured it would end soon and didn't give it another thought. But the money continued coming in. In my first week I made between $20 to $30. By the end of the second week I had a made a total of $1,000.00. In the third week I had over $10,000.00 and it was still growing. This is now my fourth week and I have made a total of just over $42,000 and it's still coming in ..... It's certainly worth $6.00 and 6 stamps!!! Also, make sure you print a copy of this article NOW, so you can get the information off of it as you need it. I promise you that if you follow the directions exactly, that you will start making more money than you thought possible by doing something so easy!

Suggestion: Read this entire message carefully! (Print it out or download it.) Follow the simple directions and watch the money come in! It's easy. It's legal. And, your investment is only $6.00 (Plus postage)
IMPORTANT: This is not a rip-off; it is not indecent; it is not illegal; and it is virtually no risk - it really works!!!! If all of the following instructions are adhered to, you will receive extraordinary dividends. PLEASE NOTE: Please follow these directions EXACTLY, and $50,000 or more can be yours in 20 to 60 days. This program remains successful because of the honesty and integrity of the participants. Please continue its success by carefully adhering to the instructions. You will now become part of the Mail Order business. In this business your product is not solid and tangible, it's a service. You are in the business of developing Mailing Lists. Many large corporations are happy to pay big bucks for quality lists. However, the money made from the mailing lists is secondary to the income which is made from people like you and me asking to be included in that list.

HERE ARE 4 EASY STEPS TO SUCCESS: --- STEP 1: Get 6 separate pieces of paper and write the following on each piece of paper "PLEASE PUT ME ON YOUR MAILING LIST." Now get 6 US $1.00 bills and place ONE inside EACH of the 6 pieces of paper so the bill will not be seen through the envelope (to prevent thievery). Next, place one paper in each of the 6 envelopes and seal them. You should now have 6 sealed envelopes, each with a piece of paper stating the above phrase, your name and address, and a $1.00 bill. What you are doing is creating a service. THIS IS ABSOLUTELY LEGAL! You are requesting a legitimate service and you are paying for it! Like most of us I was a little skeptical and a little worried about the legal aspects of it all. So I checked it out with the U.S. Post Office (1-800-725-2161) and they confirmed that it is indeed legal! Mail the 6 envelopes to the following addresses:
#1) Johnny Hart, 8412 Beech Avenue, Cincinnati, OH, 45236
#2) Peter S., 16 Lorraine Ave Bardwell, Valley NSW 2205 Australia
#3) P. Zaond, 675 Alvarado Ave. apt# 1, Davis, CA 95616
#4) Christopher Var, 17 Ponagansett Ave, Providence, RI 02909
#5) S. Cynthia, 6358 55th Ave N, St. Petersburg, FL 33709
#6) Chris Soa, 20 Matson Ave, Providence, RI 02909
NOTE: MAILING THE MONEY IS A VERY CRITICAL STEP IN THIS WHOLE PROCESS. IF PEOPLE DID NOT MAIL THE MONEY, THIS WHOLE THING WOULD NOT WORK. $6 IS NOT WORTH MESSING THIS SYSTEM UP, AND IT ONLY TAKES ABOUT 10 MINUTES OF YOUR TIME. DO THIS AND YOU WILL BE REWARDED. I AM LIVING PROOF!!
STEP 2: After you have mailed the envelopes, now take the #1 name off the list that you see above, move the other names up (6 becomes 5, 5 becomes 4, etc...) and add YOUR Name as number 6 on the list.
STEP 3: Change anything you need to, but try to keep this article as close to original as possible.
STEP 4: Now, post your amended article to at least 200 newsgroups. (I think there are close to 32,000 groups) All you need is 200, but remember, the more you post, the more money you make! This is perfectly legal! Keep a copy of these steps for yourself and, whenever you need

money, you can use it again, and again. PLEASE REMEMBER that this program remains successful because of the honesty and integrity of the participants and by their carefully adhering to every step in the directions. Look at it this way. If you are a person of integrity, the program will continue and the money that so many others have received will come your way. NOTE: You may want to retain every name and address sent to you, either on a computer or hard copy and keep the notes people send you. This VERIFIES that you are truly providing a service. (Also, it might be a good idea to wrap the $1 bill in dark paper to reduce the risk of mail theft.) So, as each post is downloaded and the directions carefully followed, six members will be reimbursed for their participation as a List Developer with one dollar each. Your name will move up the list geometrically so that when your name reaches the #1 position you will be receiving thousands of dollars in CASH!!! What an opportunity for only $6.00 ($1.00 for each of the first six people listed above) Send it now, add your own name to the list and you're in business! ===

HOW TO POST TO NEWSGROUPS --- DIRECTIONS --- ===
Step 1) You do not need to re-type this entire letter to do your own posting. Simply put your cursor at the beginning of this letter and drag your cursor to the bottom of this document, and select 'copy' from the edit menu. This will copy the entire letter into the computer's memory.
Step 2) Open a blank 'notepad' file and place your cursor at the top of the blank page. From the 'edit' menu select 'paste'. This will paste a copy of the letter into notepad so that you can add your name to the list.
Step 3) Save your new notepad file as a .txt file. If you want to do your postings in different settings, you'll always have this file to go back to.
Step 4) Use Netscape or Internet explorer and try searching for various newsgroups (on-line forums, message boards, chat sites, discussions). SUGGESTION - search, download, install 1 or several programs like "Message Board Blaster" which will find over 40,000 newsgroups for you to post this message.
Step 5) Visit these message boards and post this article as a new message by highlighting the text of this letter and selecting paste from the edit menu. Fill in the Subject, this will be the header that everyone sees as they scroll through the list of postings in a particular group, click the post message button. You're done with your first one!
Congratulations...THAT'S IT! All you have to do is jump to different newsgroups and post away, after you get the hang of it, it will take about 30 seconds for each newsgroup! **REMEMBER, THE MORE NEWSGROUPS YOU POST IN, THE MORE MONEY YOU WILL MAKE!! BUT YOU HAVE TO POST A MINIMUM OF 200** That's it! You will begin receiving money from around the world within days! You may eventually want to rent a P.O. Box due to the large amount of mail you will receive. If you wish to stay anonymous, you can invent a name to use, as long as the postman will

deliver it. **JUST MAKE SURE ALL THE ADDRESSES ARE CORRECT**
Now the WHY part: Out of 200 postings, say I receive only 5 replies (a very low example). So then I made $5.00 with my name at #6 on the letter. Now, each of the 5 persons who just sent me $1.00 make the MINIMUM 200 postings, each with my name at #5 and only 5 persons respond to each of the original 5, that is another $25.00 for me, now those 25 each make 200 MINIMUM posts with my name at #4 and only 5 replies each, I will bring in an additional $125.00! Now, those 125 persons turn around and post the MINIMUM 200 with my name at #3 and only receive 5 replies each, I will make an additional $626.00! OK, now here is the fun part, each of those 625 persons post a MINIMUM 200 letters with my name at #2 and they each only receive 5 replies, that just made me $3,125.00!!!
Those 3,125 persons will all deliver this message to 200 newsgroups with my name at #1 and if still 5 persons per 200 newsgroups react I will receive $15,625,00! With an original investment of only $6.00! AMAZING! When your name is no longer on the list, you just take the latest posting in the newsgroups, and send out another $6.00 to names on the list, putting your name at number 6 again. And start posting again.
The thing to remember is: do you realize that thousands of people all over the world are joining the internet and reading these articles everyday? JUST LIKE YOU are now!! So, can you afford $6.00 and see if it really works?? I think so... People have said, "what if the plan is played out and no one sends you the money? So what!
What are the chances of that happening when there are tons of new honest users and new honest people who are joining the internet and newsgroups everyday and are willing to give it a try? Estimates are at 20,000 to 50,000 new users, every day, with thousands of those joining the actual internet.
Remember, play FAIRLY and HONESTLY and this will really work.] ** By the way, if you try to deceive people by posting the messages with your name in the list and not sending the money to the rest of the people already on the list, you will NOT get as much. Someone I talked to knew someone who did that and he only made about $150.00, and that's after seven or eight weeks! Then he sent the 6 $1.00 bills, people added him to their lists, and in 4-5 weeks he had over $10k. This is the fairest and most honest way I have ever seen to share the wealth of the world without costing anything but our time!!! You also may want to buy mailing and e-mail lists for future dollars. Make sure you print this article out RIGHT NOW! Also, try to keep a list of everyone that sends you money and always keep an eye on the newsgroups to make sure everyone is playing fairly. Remember, HONESTY IS THE BEST POLICY. You don't need to cheat the basic idea to make the money!! GOOD LUCK to all and please play fairly and reap the huge rewards from this, which is tons of extra CASH. Please remember to declare your extra income. Thanks once again... LEGAL? ? ? (Comments from Bob Novak who started this new version.) "People have asked me if this is really legal. Well, it is! You are using the Internet to advertise your business. What is that business? You are assembling a mailing list of people who are

interested in home-based computer and online business and methods of generating income at home. Remember, people send you a small fee to be added to your mailing list. It is legal. What will you do with your list of thousands of names?
That's up to you." So, build your mailing list, keep good accounts, declare the income and pay your taxes. By doing this you prove your business intentions. Keep an eye on the newsgroups and when the cash has stopped coming (that means your name is no longer on the list), you just take the latest posting at the newsgroups, send another $6.00 to the names stated on the list, make your corrections (put your name at #6) and start posting again.
NOTES: * 1. In some countries, the export of the country's exchange is illegal. But you can get the license to do this from the post office, explaining the above statements (that you have an online business, etc. You may have to pay an extra tax, but that's OK, the amount of the incoming money is HUGE!
And as I said, a few countries have that restriction. *2. You may want to buy mailing and e-mail lists for future dollars. (Or Database or Spreadsheet software.) *3. If you're really not sure or still think this can't be for real, please print a copy of this article and pass it along to someone who really needs the money, and see what happens. *4. You will start getting responses within 1-2 weeks, it depends. ***ALSO REMEMBER*** SEND YOUR $1 OUT TO EVERYONE ON THE LIST, EVEN IF THEY ARE NOT FROM THE U.S. WHAT ARE YOU WAITING FOR??? GOOD LUCK!!!

'tis possible that it could have that kind of gain, as the reference point (compared to Dipole (dBD), Isotropic (dBI), or WET NOODLE dB(?)) was neglected in the gain statement! In fact might be even better than 27 dB (?) when compared with a wet noodle, but that has no bearing on any credible gain! That ANY antenna would have a gain of some 400 TIMES a dipole, or even an isotropic (Point source) would take up considerable acreage at 2 meters! A typical moonbounce station uses about 20 dBD gain , and these are multiple yagi antennas.
see: http://www.bigskyspaces.com/w7gj/longyagi.htm for a 19 dBD gain 2 meter yagi, and note the length! (98-1/2 feet long!)
and also look for VE7BQH - These guys have verifiable antenna gains and know their stuff! when ANY antenna claims more than 10-11 dB I gain ,be very suspicious of the claims, also, make sure to see WHAT that gain is compared (referenced) against! This is at least one of the reasons that the ARRL is loath to allow gain claims by advertizer, unless they have been verified by independant sources. Jim NN7K

So you are saying it wont matter?

I was wanting to use the marine battery I have but someone else posted
a negative experience with the fumes ruining part of their house and
their own health. It scared me a little.

I was looking at power supplies on ebay and some of them stated 12
volts (older ones) some said 13.8. That is why I asked.
I am still a little confused on what way I need to go.

As far as I know, 100% of supplies sold for ham use are 13.8V, or
thereabouts. 12 Volts was a standard voltage for many linear ICs, along with
15 V. My Astron switching supply came set for 14.05 V. I don't see that as a
problem because all my stuff can be used in a car, and I have never seen the
car voltage drop below 14 V with the engine running.

Would a cb antenna made out of fiberglass be less likely to get hit from lightening on a roof as compared to aluminum?

I am looking up info on grounding my ham radio for the base station. I am wanting to use a cb radio up there too but it would get very expensive buying a coaxial gas tube ground for my two antenna ham radio and my cb.

How many of you actually use these for the coax?

Starting with a new battery, I have used a 12v marine deep-cell with small
float-charger to power a 25w VHF transceiver for over two years. For short
periods, this will handle 100w xmit on an HF rig that draws 20-30amp. When a
charger is connected to a battery, adequate ventilation must be provided,
and the smoking lamp is "out". There is nothing wrong with using an
emergency backup battery as part of normal (indoor) operations. It will
provide hundreds of hours of monitoring and several minutes of low-power
transmit w/o requiring a charge.

You are welcome to explore some cost/benefits of lightning protection here:

http://members.cox.net/pc-usa/station/ground0.htm

Disconnecting all power supplies, radios and antennas (then grounding them)
has it's pro's, up to a point, and only you can decide this based on your
individual circumstances.

THATS IT! the ultimate reference. I hereby dub that measurement the dBwn
which will from now on be used to get the best gain figures for advertising
in anything except QST.

First, mine is not constantly connected to the charger. When it is, I have a window open and a fan circulating air in the station. Battery vents in an automotive or outdoor environment often become sealed-shut. This is not the case with a clean battery used indoors-only. A very small amount of moisture is sometimes visible on the surface of the battery around the vents following use of a powerful charger. This has never been my experience from the trickle-charger, however. Keep the battery surfaces clean, verify that the vents exist, then leave them in their normal (not loosened) condition and all is well. Not all batteries are vented and I would avoid using any charger indoors in that situation.

1419. Antenna modeling

Newsgroup: rec.radio.amateur.antenna
Date: 2005-01-26 00:21:57 UTC
From: art <aunwin@insightbb.com>
Message-ID: <1106698917.049426.54910@c13g2000cwb.googlegroups.com>
Source record: 83058

My understanding of antenna modeling is that sharp corners or
connecting points should be avoided as they can create errors.
The question I ask is what constitutes a sharp angle ?
I am assuming that it is the capacitance at the connection is the
problem. If so
is the corner of a quad a problem or is a delta feed point on a dipole
a problem ?
I see many instances of quads being modeled and also " V" wire antennas
each without a correcting "gusset" at the corners. So when is an angle
termed to be sharp?
Regards
Art

When it is at a current maximum. At a voltage maximum it's irrelevant.
Just my opinion.

>12 volt power supply will it put out the same wattage at the radio?

THe owner's manual of most radios will give you a range of voltages;
for example, one of my Icoms recommends 13.8 volts, plus or minus 15
percent. Check your manual, if you have it, or try to get a copy from
one of the internet places that sell such things.

Hi Don,

Well it seems in the interim, you got good advice as to battery use in the shack, and shabby advice about writing. ;-)

For the record, my batteries are actually sealed lead-acid Hawker Energy (Gates) Cyclon BC Cell (25 AH) and not cheap - but then they are rock solid. I went this direction knowing full well most batteries die because of one cell failure - this way I can replace the dead cell. My buddy used a deep discharge battery that was over floated (probably 15V) and he rarely minded the water level (too bad too) as he boiled it down. There was some obvious corrosion near the battery (sitting open to the environment, and he's a heavy smoker) but nothing widespread (his battery sat in a plastic tray on a wooden shelf).

During normal use at field day, my batteries lasted many hours. When the rig began to sputter, I swapped one out to charge from the car. I also monitored the voltage, and rarely ran below 11.5 Volts. Even with a "quick" charge, I would always current limit it to about 5A.

Hi Art,

Kinks (aka sharp bend) add inductance.

>I see many instances of quads being modeled and also " V" wire antennas
>each without a correcting "gusset" at the corners. So when is an angle
>termed to be sharp?

It is not generally an issue because the greater bulk of the antenna
swamps out this small perturbation. It is the modeler that has the
problems. Consult your user's manual that cites considerations to be
taken for wires joining at an acute angle. Follow the rules offered.

On second thought, it's all irrelevant. The feed lines of a balance feed attach at the center of the dipole. That's a right angle bend at a current maximum. Must not be a problem - everybody does it - Hi!

lIif you look at lamina flow on any corner there is a change because
the cross sectional area changes rapidly.. My particular programm
suggests that the point of resonance changes because of this and thus
inserts a 'corrective' action.. What this action is I do not know..
In the past I have always cut corners with a conductive member so as
to cut the intersecting angle by half., but this does not appear to
be followed in demonstration articles.
After musing over this question for some time. and without further
knoweledge, I would discount any modeling results of a fractal type
antenna which is a worst case scenario.
of kinks and bends.and corresponding cross section changes.

I was wanting to use the marine battery I have but someone else posted
a negative experience with the fumes ruining part of their house and
their own health. It scared me a little.....

I've been using batteries in the house for 15 years or longer. Never a
problem,
and I've never noticed the fumes. You only get heavy fumes when really
heavily
charging, or when overheating, from overcharging. I use a 12/2 amp
automatic
charger to keep the battery up. It's on 24/7. The only real drawback to

batteries is the corrosion that builds up. It's no big deal really, but
it does
have to be cleaned off from time to time, and also the connectors will
need to
be cleaned from time to time. That crud is highly corrosive, and
probably would
eat/stain carpet, etc...So keep the battery on some kind of pad, if not
in a
battery case. I have an inverter for emergency 117v use...Have used it
quite a
few times when the lights go out do to powerline problems, blown
transformers,
etc..I'm still on the air, plus can use a lightbulb, watch TV, etc..MK

P.S. When using batteries, always use the proper safety
precautions...Batteries
can explode. Don't unhook, hook hot radios, chargers, to cause a spark.
Turn
them off first, hook up, and then turn back on. When I hook up my
icoms, I have
to actually unhook the cable from the back of the radio, if I don't
want a spark.
The finals are always hot on the icoms, and will draw current/make a
spark, even
with the radio off. So I'll hook it all up, and plug the cable to the
706 last.
My IC-730 is the same way. Blowing up a battery in the house could be
nasty...
But saying that, I wouldn't let that scare you...I've never had a
problem...You
can always keep it in a battery case, under a table, etc, for extra
protection.
MK

>simple equipment be.

Hi Mike,

One of the "best of class" questions.

A test that would work at the most fundamental level would measure the conversion of RF to heat.

Let's take one bead whose characteristic Resistance is 25 Ohms, substantially the same as the Z of a quarter wave antenna. Instead of adding this bead surrounding the transmission line of the antenna (its usual, purposeful application) we place it on the radiator at the base. This adds 25 Ohms to the 37 Ohm native Radiation Resistance, and thus the bead "should" absorb roughly half the power (what ever you throw at the antenna typically).

Of course this is all hip-shot math, but the details contain so many variables that this post would become encyclopedic if I attempted to go to that granularity. Suffice it to say that the more important discussion lies in the how and what, not the how much.

How? Measuring the heat of a bead may not be straightforward if you were to attempt this directly with a surface temperature measurement. So better, measure it in a bath of water. The experimental sophistication goes up, but conceptually remains rather simple. You now have to brush up on your understanding of the caloric bomb. Others may head for the exit to buy a "better" solution, but the caloric bomb remains one of the most accurate methods available to even the guys with money to "burn" on figuring this out.

Going further, you may discover that there's just not enough heat to gear up to with your thermometer. Well, now it becomes time with the What. Boost the ante and use a fever thermometer (after first elevating the bath temperature) but now you have to calculate how to build a bath with a small enough time constant but high enough isolation from the otherwise "cooler" environment. If this is getting a bit too much, try boosting the heat generation (wrap the radiator through the bead to raise its loss resistance by the square of turns).

This caloric method will lead to an absolute evaluation of the bead R. Finding the relative evaluation of the bead R will probably provide

more resolution. Comparisons are easier to make too. However, barring having a known sample bead to compare to, you are left to ask yourself "yes this is better, but is better good enough?"

How could you do a relative test? Take the same scenario above (the bead surrounding the radiator of a quarterwave vertical) and take Field Strength readings as you change beads. The best bead is evidenced by the poorest Field Strength. Is best enough? Well....

Is it sensitive enough? Try the same turns ratio boost described above (but it will still not resolve if that particular bead is good enough).

The list could go on, but the two above evidence: Power, Current/Voltage/Resistance. There's not much left which is not a variation on a theme (which returns us to How). I hope you note that this requires only a thermometer or FSM which qualify as simple equipment. Give me a bigger budget, and it will only increase cost to no measurable increase in accuracy. You might have the advantage of seeing the answer on a digital display - but who's to say that it is actually right, much less close?

Modeling of wires connected at an angle is a problem only with MININEC-based programs such as AO or ELNEC, not with NEC-2 based programs like EZNEC or most other modern programs.

The problem with wires connecting at an angle is that MININEC "cuts the corner" -- it acts like a wire extends between about the middles of the corner segments, rather than going clear to the corner as they should. The problem gets less and less as the segment length gets shorter and shorter near the junction (since the distance "cut" is less), or as the angle gets more obtuse. There's no magic threshold where the problem suddenly occurs (same reason). Its seriousness depends entirely on how serious a small length error is -- it'll just shift the resonance slightly of a single loop modeled with a moderate number of segments, but it can seriously alter the pattern of a quad because of the sensitivity of the parasitic element(s) to small wire length changes.

ELNEC had a way of correcting for this, called "segment length tapering", where it would automatically convert a wire into a series of wires with increasing segment lengths. That way you could have a very short segment at the corner, but not have to use a large number of very short segments for the whole antenna. That feature is still in EZNEC. It's no longer needed for this purpose because NEC-2 doesn't have the problem, but it's occasionally useful at other times.

You can find out more about this phenomenon in "MININEC: The Other Edge of the Sword", in Feb. 1991 _QST_.

Hello...,

Just released the latest new 5.5 version of the 4nec2 freeware antenna modelling package. Now capable of running both a Nec-2 or a Nec-4 engine.

See http://www.si-list.org/swindex2.html

Note however that in order to run Nec-4 you need a license from LLNL.

73's,
Arie.

Does anyone know where I could get plans for a 440 yagi that uses a conductive boom and is designed for 50 ohms?

I have seen plans but all of them use an insulated boom or insulated elements.

If i use a conductive boom and ground it, is there no need for a coaxial lightening arrestor?

I don't know what other's opinions will be regarding this, BUT - mine is NO. I know a guy who fried a H.F. radio twice by doing that. Maybe he didn't have it connected altogether properly, but the charger fried his radio twice and it cost him a few bucks to get it fixed both times. The first time, he didn't say what caused the failure. The second time, he figured out it had to be the charger. Since he quit using the charger at the same time - once the set was repaired - again, the set has worked fine. And yes, he still uses the battery and a charger. He just disconnects the charger before using - now.

I have a marine battery charged by an Astron RS-20M and a 75w solar panel.
I monitor the battery voltage and shut off the charging system when the
battery
is charged. That decreases the possibility of battery failure.

Same ones I use! :)
Floated across a switchmode 15A charger set to 13.8V.
Been in service for 6 or 7 years with no trouble.

I added an "aw shit" fuse at 60A between the middle terminals at the 6V
point, and it has a couple of hefty outputs ending in powerpoles.

Only if the charger isn't set properly.

What we're doing is called "float" service, where the charger voltage is set lower than it would be for normal "recharge a dead battery" sorts of applications. You have to check your particular battery's spec, but most sit around 13.8-ish instead of the normal charger output of about 14.4.

Well, there's all sorts of junk out there called "chargers", and most are not designed to be on the battery continuously, and some don't have any output voltage regulation at all. Wouldn't surprise me at all, if he connected the radio to the "charger" without a battery in place, and got 18-25V or so applied to the radio.

For this sort of service, you want a unit with regulated output voltage, and a trim adjustment.
I use switchmode because it's way more efficient, and therefore runs with no observable heat.
There is no noise or hum into the radio, even when it's putting full output into the battery.

My Samlex charger works nicely, and will deliver 13.8V to an open circuit, or a 1 ohm load.

1445. Odd observation - nonresonant beam

Newsgroup: rec.radio.amateur.antenna
Date: 2005-01-26 15:22:55 UTC
From: Bill Ogden <wogden@attglobal.net>
Message-ID: <ldOJd.33178$9Q3.28125@fe09.lga>
Source record: 82984

I have a new SteppIR antenna to play with and I noticed an odd response. If I set the beam for 17 or 15 meters but listen on 20 meters I seem to have a better S/N ratio on signals. If I then switch the beam to 20 meters (while continuing to listen on 20) the background noise and the signals go up but the noise goes up more than the signals.

Expressed another way, is a non-resonant antenna sometimes better for reception than a resonant antenna?

This may be a well-known effect, but it is new to me.

Bill

I wouldnt plan on avoiding lightning protection, just by useing a conductive boom, nor for that matter, even loop (electrically short circuit to DC) feed for ANY antenna! When lightning strikes, it is going where ever it wants to, in spite of the best grounding intentions Remember, that if lightning can travel a mile, in open air, it will go where it wants when it hits an antenna! tho the bulk of the energy will disperse to ground, there is always SOME thjat will go down the coax , even in a close strike! And whan that happens, dammage will occur, especially without protection. I remember working on a base station during a storm, haveing removed an antenna- the coax was some 1 inch from the edge of the base station, and produced a spark (Ill let you figure the voltage at that point) , and that wasnt even a direct hit-- the strike occured some 3-4 miles away! Look at it like an insurance policy- 50 to 100 bux is cheap when talking about replaceing a FT-847 (or other expensive rig). "Course the best protection would be disconnect the radio, and ground the coax. But then there is still no garentee. Jim NN7K

Is it possible to make a coaxial surge supressor? Are there still plans
that use a metal boom? What about static electricity?

I didn't see the actual charger the guy used, but when the rig fried the 2nd time and he fessed up with his hook up, then I questioned the voltage. He didn't fess up the first time as he felt it was hooked up ok and there was nothing to have caused it aside from a "radio" failure. In his mind, it was a "12 volt charger" - it should have worked - must have been the radio." And all he said was - it was hooked up to a battery. Saying nothing of the charger since he felt it wasn't at fault. His charger was putting out close to 18 VDC - when I asked him to check it - via phone. So, I told him, there is your culprit. As to how well it was "supposed" to be regulated, I don't know - but, he learned a lesson that time - an expensive lesson. "I" realize - all power supplies and chargers aren't created equal - he didn't - he was just getting into Ham when that happened. He seen a diagram I guess, but it said nothing of voltages or other hazards to avoid. So, he followed it and whalah - snap, crackle, pop. At the moment, it did seem it could have

been a "radio" failure meaning a part "could" have went bad from age/use - possible former abuse - the set was used when he bought it. AND according to him, it didn't blow right away, which sort of masked the fault - aside from the concealing the charger. When it went south the 2nd time almost immediately, then there "had" to be a reason to have caused it. Once the culprit was found, the radio repaired - again, he's had good use of it since.

Good News!

Do you know how simple it is to go to Heaven after this life has ended?

Some people believe that belonging to a local church, temple, mosque or synagogue will get them to Heaven.

Others believe that water baptism, obeying the ten commandments or just being a good person will get them to Heaven.

There are many other beliefs as well, but the good news about God's way to Heaven is found in the Holy Bible.

The good news is that God came from Heaven to earth in the person of Jesus Christ over 2000 years ago and died for our sins(misdeeds). He was born in the land of Israel supernaturally to a virgin Jewish woman named Mary. He lived a sinless life for thirty-three years and then sacrificed His sinless blood and died on a cross to pay the death penalty for our sins. After Jesus was placed in a tomb He rose from the dead three days later as He said He would. The Holy Bible also tells us that Jesus Christ ascended into Heaven and that all who accept Him as their Lord and Saviour will live forever with Him in Heaven where there is no more death, sorrow, sickness and pain.

The Bible says, "For the wages of sin is death, but the gift of God is eternal life through Christ Jesus our Lord." (Romans 6:23)

This verse in the Bible says, "For ALL HAVE SINNED, and come short of the glory of God." (Romans 3:23)

This verse says, "But God demonstrates his own love for us in this: While we were still sinners, Christ died for us." (Romans 5:8)

In this passage the Bible clearly explains how simple it is to be saved and on your way to Heaven, "For if you confess with your mouth, "Jesus is Lord," and believe in your heart that God raised him from the dead, you WILL BE SAVED." (Romans 10:9)

You can be saved right now and on your way to Heaven if you will open your heart to Jesus and pray the following prayer:

Dear Jesus Christ, I want to be saved so that I can have a home in Heaven when I die. I agree with You that I am a sinner.
I believe You love me and want to save me. I believe that You bled and died on the cross to pay the penalty for my sins. I believe that You rose from the dead. Please forgive my sins and come into my heart and be my Lord and Saviour. Thank You Lord Jesus Christ for forgiving me and saving me through Your merciful grace. Amen.

You are now a Christian if you said the prayer and allowed God to save you. Welcome to the family of God.

Salvation is not a reward but a gift. The Bible says it this way, "For it is by GRACE you have been SAVED, through FAITH and this not from yourselves, it is the GIFT of God." (Ephesians 2:8)

Nothing in the world is more important than your eternal destiny.

The Bible says, "In Him(Jesus) we have redemption through His blood, the forgiveness of sins..." (Ephesians 1:7)

If you have not yet made a decision to be saved, please do so now before it is too late. The reason why it is so important to be saved now is because you do not know exactly when you will die. You may die prematurely in a traffic accident, terrorist attack or some other way before you get another chance to be saved.

The Bible tells us that we will spend eternity in Heaven or a place of eternal torment called Hell. It would be terrible to die and go to Hell when all you have to do is accept Jesus Christ as your personal Lord and Saviour.

Some people that have already made Jesus Christ their Lord and Saviour worry about losing their salvation. The Bible teaches Christians that we can never lose our salvation no matter what happens.

The Bible says it this way, "My dear children, I write this to you so that you will not sin. But if anybody does sin, we have one who speaks to the Father in our defense Jesus Christ, the Righteous One."

Yes my friend, Jesus Christ is able to save you and keep you saved.

Please tell your family and friends, thanks!

Have a great day!

"If I use a conductive boom and ground it, is there no need for a coaxial lightning arrester?"

That is my experience, provided that the driven element is a short-circuit for lower frequencies, such as a folded dipole or a short-circuit 1/4-wave stub.

My company had countless examples in high places over the world with no damage to radios, including many solid-state models, operating 24-7.

W6SAI, Bill Orr gives plenty of examples of "plumber`s delight" Yagi-Uda antennas in the eighteenth edition of "Radio Handbook" (1970). He also warns on page 548: "Short large-diameter elements have low Q and are not practical in parasitic arrays. Orr also says: "The Yagi antenna, however, remains "the antenna to beat" for the 50-,144-, and 220-MHz amateur bands."

Best regards, Richard Harrison, KB5WZI

That's what I suspected, unregulated output, without the battery in the loop
to absorb the energy.

This comes from using a "charger" as a regulated power supply.
Note that a regulated power supply makes a much better charger, than even a
"charger".

Hi Don,

Well then, I must presume it is the inferior product to blame (or perhaps inferior advice). Take note that Dave has an identical installation and we both suffer no problems whatever and this is for YEARS of sustained service.

Hawker guarantees my cells for 15 Years of life and fully recommends a continuous float charge. There are probably 100 Million batteries in hospital corridors, schools, churches, theaters, public service buildings all sitting there on a float charge waiting to turn on the emergency lighting. In fact my current limiting of the quick charge is overly conservative as Hawker explicitly offers there is no restriction to inrush current from professional grade chargers.

Lou's report of his buddy's charger running at 18 V is nothing short of a death wish with a meter indicator. If you read the precautions printed on that charger's box, it also says it is dangerous to charge an automotive battery with it while the battery is still connected to the automotive electronics.

If you choose to employ cycle charging (where you disconnect the charger and run the battery down), then you need to run at a higher charge voltage which is typical of most chargers off the shelf for automotive work where you are doing a battery overnight. The higher voltage is NOT GOOD for floating - unless you have deep pockets for battery replacement. In the case of automotive batteries, their ONLY use is to start the engine. After that, they are little more than a chemical capacitor for the alternator's supply to the automotive electrical system. In the old days, better cars had a dash mounted Ammeter. The plus indication showed a slight positive indication for the alternator load (charge and ignition in the days before megawatt stereo systems); or a negative indication when you were running on battery alone (and your -well in this case, and age- generator was shot).

Hi Bill,

It seems highly unlikely there would be any alteration of S+N/N by a passive device. More likely is trusting your senses to make this kind of measurement (which is a poor standard).

Perhaps you can testify this was observed by S Meter readings. Well, even then, this is another failure in trust unless you have calibrated your S Meter against a known standard. Problem is that most S Meters are not linear against their own scale.

This is all a function of the actual ratio being distorted as the overall levels climb through the meter readings. Let's consider if you started with S3-S5 (noise-signal+noise, a presumable 6dB separation) and pushed that up through tuning to achieve S7-S8(a presumable 3dB separation) then you need to confirm your meter. Is the S3-S5 separation in fact twice the S7-S8 separation? Feel free to substitute your own readings (if in fact you based your observations on this method). The further apart the readings, the more likely you are to suffer the distortion of meter scaling inaccuracy.

What do you mean it is "short circuited for low frequencies?"

I am trying to decide whther to go with two antennas or one.

I would like to build at least one of them, but can not find plans for
one with a conductive boom.

Jim, NN7K wrote:
"When lightning strikes, it is going where ever it wants to, in spite of the best grounding intentions."

Yes, the trick is to send it to where you would rather it goes. You do this with your grounding techniques.

The coax itself is important protection against lightning. Opposition within the coax to lightning is severe. Lightning is a common-mode phenomenon. Lightning takes the easy path on the outside of the coax. All coax has a flashover potential which depends on its spacing and the dielectric of the coax. Once it flashes (not far within the coax) the voltage is clamped to the sustaining potential of the arc. This is a steady low potential with a very high conductance in the arc.

Lightning on the outside of the coax must be properly diverted to ground to avoid damage.
A few twists and turns in the coax increase its opposition to the lightning (a transient) on the outside of the coax. Such a coil is advisable between the antenna support and your operating position. Let the antenna tower carry the lightning to the earth.

Best regards, Richard Harrison, KB5WZI

Not expressly addressing your circumstances: But, I sometimes will
switch to a different antenna on receive to get a better S/N ratio --
even if the sigs drop in level.

E.g., When on 15M, I might switch to the 80/40M dipoles for RCV.
Or, when on 80M, I might switch to the tri-bander for RCV.

(Then, like a klutz, I'll forget to switch back on XMIT. :-)

Stryped wrote:
"What do you mean it is a "short-circuit for low frequencies?"

A folded dipole, you might agree, is essentially a short-circuit for d-c, also for 50-60- Hz a-c. At some high frequency, the folded dipole is no longer a short-circuit, but offers considerable opposition to current at its input terminals.. Its impedance is very high at its first resonance where its overall length is 1/4-wave, and its impedance is often about 300 ohms near its second resonance where its overall length is about 1/2-wave.

At frequencies much lower than the resonant frequencies of the dipole (most of the energy contained in a lightning stroke) the opposition of the folded dipole is very low, or almost a short-circuit. This puts the voltage at both terminals of the dipole to the same value and makes the lightning applied to the transmission line a common-mode phenomenon.

Best regards, Richard Harrison, KB5WZI

1462. Tuned dipole Q:

My 160/80m trap dipole can be operated without
a tuner from <1.800 to 1.930. I mainly operate in
that range (usually on 1.893) and I have a tuner for
operating above 1.930. Easy.

My question is this - is it better to resonate high and
use a tuner to go lower or do it the way I'm doing now
(resonate low and use a tuner to go higher)?

Or will it even matter enough to notice??? My guess
is (at these freqs) no......

Dear Ken,

Your trap dipole is resonant only in the sense that you see
approximately 50 + j 0 ohms at the input to the feedline. I will
assume that it is not actually of the length of a "resonant dipole"
(about 260 ft.).

Therefore, we are talking about a "resonant" antenna/feedline
"system".

The next issue is the radiation pattern of the antenna. Regardless of
how you use it (i.e., with or without a tuner), it will have a pattern
that is a function of its configuration and operating frequency.
Whether or not a tuner is involved is not a factor.

The only real issue is efficiency. Everything else being equal, the
tuner is going to rob you of some of your power. How much will depend
on many factors - the primary ones being the actual impedance seen by
the tuner and the specific design of the tuner - especially its
inductor.

Therefore, it would appear that you are doing the best thing - namely,
to use the tuner only when you have to.

Richard- the point I make-and the company I worked for, until I retired on disability- has Thousands of base stations- and yet still sustains major damage every year-- they have a manual on grounding, and a 2 week program on grounding/insulateing and , in fact have so many grounds that the wonder is they dont have major problems with ground loops! That company is Union Pacific Railroad. If you can find a employee of the communications dept, you might ask to borrow a copy of it. It is interesting to read, just for information's sake. One thing that I DIDN'T point out (as it has no bearing to grounding antennas an a ham (or normal business) environment, is that because of Federal Railroad Administration rules, that in many applications (primararily involveing switching equipment), that any GROUNDING is strictly prohibited! As most signals are now either radio controlled, or soon will be (the old open wire "Code Line" is being rapidly retired), this brings new meaning to ISOLATION for the radios/antenna , via the RS-232 bus to the Coder logic-- a forest, if you will, of Opto-Couplers at each site. This also applies to "Talking hot box,dragging equiptment, weight in motion, and Automatic Car Identification eqpt! Even where phone cables cross under/over the tracks brings new meaning to arcing in a lightning storm. Had one here in the yard, that was a dead cable (cut off at both ends) when lightning struck (not even anywhere near the cable/tracks) you could see arcing between the pairs (talk about induction!) The length of that cable was about 500 feet! The protectors that U.P. recommends (and buys by the hundreds is poly-phasor , tho for my own use like the Alpha Deltas. The Alpha-Deltas use standard gas protectors as are in telephone circuits, and break down at 200, and 300 volt levels- while the polyphasor measure a wide open at the center conductors of your 2 pieces of coax The difference is the Alpha Delta is a relatively broad band device, while there are several different models (depending on freq. for the Poly-phasors. The point that I was trying to make (perhaps poorly), is :1) WHEN you sustain a DIRECT HIT, something is going to happen - and that wont be good news, except to the parts jobbers/manufacturers and 2) Even a nearby strike can leave great damage if no preventive measurs have been taking to isolate the antenna from the radio. If you open the preamp of a 150 MHz motrac, you see a neon lamp-- that was for protection of a nearby strike, but for a direct hit-- doesnt do a lot of good! as info, Jim NN7K

However, I would like to see an answer to his question:

1. Is it best to cut "high" and tune for "low" when necc.?
-or-
2. Is it best to cut "low" and tune for "high" when necc.?

-- when operating on a band (i.e., 75/80M or 160M) where a 50 to 100 kcs. shift in freq. is a large'ish percentage change in wavelength.

3. ..or, is it Mox Nix?

I read somewhere that as the length of each leg of the dipole approaches 5/8 wave the gain increases.
(The reason for the 5/8-wave vertical)
So - from that - I would gues you'd have a smidgen better antenna by cutting it long and tuning to match.
But for the record - I would cut it so as to use the tuner less often.

Source record: 83007

My observation was based entirely on my ears --- a very subjective measurement I know. However, the effect was rather striking. It might have been due to the high noise crashes (when the beam was tuned to the "right" band) that create more subjective interference due to overloading the ear.

I have heard from others now who mention that using the "wrong" antenna sometimes appears to improve signal readability. (Of course, this could be due to polarization differences, etc, etc, that are probably not involved with the SteppIR setup.)

It is all very subjective and probably not worth a technical debate. However it would be tempting to utilize the effect if the band changes on the SteppIR were just a bit faster ---- an if I could remember to retune the antenna every time before transmitting.

Like most of us, I have noted many times that the ability to clearly copy a signal (i.e., a comfortable S/N situation) is often not correlated with S meter readings of the signal or the noise.

"The radio says 13.8 v dc but if I get a 12 volt power supply will it put out the same voltage at the radio:"

No. All supply cables have an IR drop.

Automobiles supply a d-c voltage to charge the battery which cranks the engine and supplies the accessories when the engine is off.

SETTING THE VOLTAGE REGULATOR IS A PROBLEM. iT MUST BE SET HIGH ENOUGH TO TOP OFF THE BATTERY AND LOW ENOUGH NOT TO BOIL THE BATTERY WATER AWAY (OUTGASING).

To complicate matters, at least four different automobile battery constructions are used. All have different ideal charging voltages at the same temperature and for the same use.

Battery and charging system manufacturers disagree with each other and even with themselves.

In the 1970`s , the low-maintenance calcium-lead battery appeared. It was designed to avoid outgasing and water addition to the battery. The original battery had had antimony added to its lead plates to strengthen them for mobilr bumps and shakes.The lead-calcium battery had calcium replacing the antimony. Battery manufacturers then had a new idea. They used antimony in the positive lead plate and calcium in the negative lead plate. They called this the "hybrid battery"

Some car makers then decided to adapt the "gel-cell" to autos. This should take no water but woiuld not like being overcharged.

I`ve had satisfactory experience with calcium-lead batteries. In several crosscountry microwave systems these were used to float on the d-c power supply. The voltage of the supply was set by experiment to a voltage which would top off the batteries so that they could run the equipment for several hours when the powerline failed but not gass so much that they frequently required water. The batteries had very long useful lives and cost much less than nicads. The cells had no memory problems or polarity reversals as the nicads sometimes did.

Best regards, Richard Harrison, KB5WZI

Try turning the AGC off, turn the RF Gain way down and the AF Gain up considerably. Then advance the RF gain until the signal is just copyable in head phones. Repeat for the two antenna conditions. Make sure your audio levels are equal.

Military and Ham operators operate this way and claim a SUBJECTIVE increase in signal to noise over that of a wide open receiver. Technically this should not be true, Signal to noise ratio should not be reduced by decreasing receiver gain

But the human ear with its threshold levels, logarithmic hearing, and brain filtering may account for this.

I never said I was an "expert", I only described my own safe use of a 12v deep cell marine battery indoors. But I notice your setup:

>I'm sitting here looking at my own setup
using a standard auto starting battery - cheap non-sealed Walmart
special

- Does NOT include a sealed battery, many of which are just cheap junk that could easily blow up with too much charge, and giving general advice to someone not knowledgeable about batteries, would be don't charge them indoors. That stands as good advice until you can demonstrate otherwise, and accept the responsibility for accidents resulting from misuse of batteries or charging equipment.

1474. roof joy-dipole help -RFI(req for info)

Newsgroup: rec.radio.amateur.antenna
Date: 2005-01-27 00:46:17 UTC
From: ml <m@di.net>
Message-ID: <m-5D7D54.19461226012005@news.verizon.net>
Source record: 83013

hi

I need some help on a few things, but please excuse my poor writing style it's a problem ...

After a 15yr petition my coop board has agreed to let me put up a dipole on the roof. wow cant wait to get really back on the bands

naturally it's contingent on not creating any interference, and being 'low profile' and finally not damaging the roof....

the part that concerns me a bit is interference...

my roof has a elevator house structure in the middle, on that is a building master antenna. looks like 20 or 30ft high

I won't be allowed to put up any poles etc, all i can do is run wire between existing stuff, there are plenty of vent pipes and such so i believe i could stretch it ok and support it fine

but it will be lower then the tv antenna. how bad is this?

my roof concern would be how to design a dipole coax fed, to minimize the chance's of interference, i guess thats the best i could do

the other concern i had was i must run the coax down thru the electrical room on each floor

14story building i am on 4thfl

their are 2 exsiting core boars i might be able to squeeze some coax into one has the rg59? u tv coax the other the direct tv coax i think also 59u

my thoughts on that are my first goal is which if any would possibly cause interference from my coax to tv?? i am guessing the sat coax would be less bothered by my rig????

however am i correct in assuming that the sat cable would be most rfi causing to me?? how would i fix this a cavity or filter???

i guess my run might be as long as 200ft or 150ft-- what would be the 'best' coax to use aka that would give off least interference and have low loss, the hole isn't going to fit anything like bigger than 8u diameter - don't know if i can afford hard line or if that would make sence given the difficulty of working w/it and $$conectors

if i can't squeeze a 2nd coax i'd still like to hide a small 2m/440 mag mount perhaps fed via a small duplexer the one's i've seen for 'car'

use arent waterproof anyone know of any that are outdoor safe??

What would be the best type of dipole to use , goal being least likely to cause tvi

i'll have to run coax to the roof , how should my dipole to coax transistion be made?? a balun of some sort? if so which?

should i have a bit of dipole to ladderline or a few coax loops??

trying to figure what would be the best ballance of

least tvi offenceive , and designed properly/efficiency

my goal is to make it for at least 160-10 (dare i try 6m?)

i'd prob try for a horizontal run, but might have to do a inv V

Any help tips or suggestions are greatly appreciated guess this is all simple stuff but i wont have easy access to the roof, so i'd like flesh out the basic desin prior to work

i am guessing that my 2nd biggest point of interf might be aside from the master tv antenna itself, is the dist amp, havn't seen it but almost positive it's the cheepest one out, anyone know of a good source for those ie brand that is super filtered/shielded so i won't overload it perhaps if i pay out of pocket for a beter unit anyone can suggest such a brand/make/model?? (presuming i cause int i'd test first)

thanks to all

That would be the inverted V you mention much later.
>

Use big coax. Put a BalUn/Choke at the end.

>but it will be lower then the tv antenna. how bad is this?

Bingo - Current BalUn (or simply an air wound one).

>my goal is to make it for at least 160-10 (dare i try 6m?)

Try to confine yourself to what is reasonable.

Run your rig at 1/2 to 2/3rds power so as to not force circuits into
maximal distortion simply to obtain gain.

Recommendation is to accept that some things just aren't meant to be. What did you do to the Coop board to change their minds after 15 years, drug them?

People who live on the 4th Fl of a condo don't take up some hobbies like diesel engine repair, boat building, or wiring a roof top dipole down 10 stories to their flat. You pretty well laid out all the impossibilities yourself, what's left for this group to offer, sympathy? You could always take your rig out to field days.

Jack

I don't consider 50 - 100 kHz to be a sufficiently large shift to make any difference. It's only 2 1/2%, which is nothing.

So, you are correct - es macht Nichts aus!

Remember, "resonance" is not all it's cracked up to be. In fact, it's almost irrelevant at the typical heights above ground encountered (45 ft or less for 80 and 160 m). I'm not saying that you do not need to cut a dipole to the frequency. What I am saying is that at low heights all the power goes straight into the clouds, anyway. The reason most people like "resonance" is for the ease of matching to the rig's output stage - not that the antenna works any better. You probably don't care in which direction in the horizontal plane the energy goes - it's going to be wrong half of the time, anyway - right?

Do you suppose, by any chance, that Louis Varney had anything like
that in mind when he invented the G5RV antenna specifically for the 20
m band with its 1.5 wavelength flat-top (about 3/4 wavelength on each
side)?

Would this method give meaningful results if used at 70 cms using the UHF range on something like a MFJ antenna analyser?

I could pop various beads onto a short piece of coax and determine the relative effectiveness, but how good would this be for absolute results?

Thanks

MikeN ZL1BNB

Back on 25/04/03 re "Choke balun impedance recommmendations" Roy Llewellan wrote:

"By all means, the slide rule is fine.

To measure the common mode impedance of a choke balun, simply wind a piece of wire on the core with the same number of turns as you'll use for the actual balun. Connect one end of the wire to the center conductor of the antenna analyzer connector and the other to the connector shell. Read the impedance at the frequency of interest. Or if you prefer, you can wind it with a short piece of the actual coax you'll be using. Connect the two coax conductors together on each end of the winding, and measure as you would with a single wire. If the impedance is out of the analyzer's range, you can use a different number of turns and the relationship that the impedance is proportional to the square of the number of turns.

Use the same method to measure a W2DU type balun (ferrite cores slipped over a coax line). If the measurement is out of range, measure a different number of cores and extrapolate -- the impedance is directly proportional to the number of cores.

Roy Lewallen, W7EL

My queries:-

Would this method give meaningful results if used at 70 cms using the UHF range on something like a MFJ antenna analyser?

I could pop various beads onto a short piece of coax and determine the relative effectiveness, but how good would this be for absolute results?

Thanks

stryped@hotmail.com wrote:

>
>
> Is it bad to leave a charger hooked up to the battery permanently.
Mine
> is a 12/2 with automatic operation.

No. Thats the whole point of the "automatic" charger. The old style
"trickle"
chargers should not be left on past full charge for long periods.
I use a 12/2 automatic, and it's on 24/7. But, same for my 706. It's
usually
on 24/7...I bought it in 2001, and it probably hasn't had a full weeks
rest
since then...When a "12v" battery thats on a charger reaches appx 14.4
volts, it's
fully charged. If you unplug the charger, or if automatic cut off, the
voltage
will drop down to about 13.8v. When it drops much lower than that, the
charger
kicks back on, charges to appx 14.4v, and cuts off...Over and
over..This manner
of charging won't hurt a battery, and can be left on all day if you
want.
A trickle charger reaches 14.4, and keeps charging, but with a lower
current
level. It won't hurt it for short periods of time, but after a while,
the battery
overheats, and thats when you start boiling off electrolyte...How bad
depends on
the charge rate...A 1 amp or less trickle charge is not near as bad as
a 3-5
amp trickle charge to a fully charged battery. But after switching to
automatic,
I could never go back to the old style manual chargers...With those,
sometimes
I would forget to cut them off...And sometimes, I would cut them off,
and forget
to plug back in, and eventually, have a dead battery...Thats worse than
overcharging..
MK

Not odd at all. The noise source is in a side lobe in one case and in a null in the other. Antenna pattern changes all
over the place as you move away from the optimum frequency of a yagi. Happens all the time. I once found a condition
where my HF tribander pulled in a 2 meter signal better than a 10 element 2 meter yagi mounted several feet higher.

>decreasing receiver gain

Oh but it should. AGC will compress differences, thus lowering the
subjective ratio in comparison to a non-AGC perception. However, the
fluctuation of all signals will be wider. Myself, I've never been
afraid of automatic circuits, but often I find they are marginal to my
interests and for weak signal detection, I follow the conventions
you've offered.

1486. Newsgroups on Decline? AOL dropping this NG

Newsgroup: rec.radio.amateur.antenna
Date: 2005-01-27 13:04:16 UTC
From: fractenna@aol.com
Message-ID: <20050127080416.12810.00000305@mb-m11.aol.com>
Source record: 82875

As a 12 year member of AOL, I note that the world's largest ISP has made a decision to drop newsgroups from it's service.

The decline of newsgroups has generally followed the tendency for this type forum to deviate dramatically from the original intent. But in the case of this NG, I too am of the opinion that it really has outlived it's intended function and time scale. It's become a rather limited BBS of sorts, with a dramatic amount of content that's either drug or sex related, or alludes to illegal activity.

No thanks.

There are a number of other forums around--hence the decline--and although antennas are a minor spark of interest, there clearly isn't the kind of activity you saw in the late 1990's, for example.

Oh well. The net antiquates many things, even parts of itself.

I'll check in once in a while to see who is still alive:-) Best to all, and drop me a line if you'd like.

73,
Chip N1IR

I'm sure you've read these letters asking you to send $1 to six different addresses. Putting your home address or mailing address on the internet can be risky, but through PayPal all you have to provide is your email address. It's safe and easy. Just go to www.paypal.com and set up your FREE account! I am not a gullible person and have never trusted things like this, but I gave it a try. Hey it's only $6. I figured at least 6 people would respond out of the millions of people that use the internet. You should give it a try too! You have nothing to lose, and thousands to gain! Read on for the letter that I found (of course, I added my PayPal e-mail on #6)...

HOW TO TURN $6 INTO $6,000+!!! THIS REALLY CAN MAKE YOU EASY MONEY!!! IT WORKS!!! BUT YOU HAVE TO FOLLOW IT TO THE LETTER FOR IT TO WORK!!!! A little while back, I was browsing through newsgroups, just like you are now and came across an article similar to this that said you could make thousands of dollars within weeks with only an initial investment of $6.00! So I thought, "Yeah, right, this must be some kind of scam" but like most of us, I was curious, so I kept reading. Anyway, it said that you send $1.00 though PayPal to each of the emails stated in the article. You then place your own email address in the bottom of the list at #6, and post the article in at least 200 news groups. (There are thousands) No catch. That was it. So after thinking it over, and talking to few people first, I thought about trying it. I figured what have I got to lose except $6.00, right? Like most of us I was a little skeptical and a little worried about the legal aspects of it. It follows the same regulations as the "mailed chain letters, which according to the U.S. Post Office (1-800-725-2161) is indeed legal! Then I invested the measly $6.00. Well GUESS WHAT!!? Within 7 days, I started getting money in my PayPal account! I was shocked! I figured it would end soon, but the money just kept coming in. In my first week, I made about $20.00. By the end second week I had made a total over

$1,200.00!!! In the third week I had over $10,000.00 and it's still growing. This is now my fourth week and I have made a total of just over $36,000.00 and it's still coming in rapidly. It's Certainly worth $6.00. I have spent more than that on the lottery!! Let me tell you how this works and most importantly, why it works? Also, make sure you print a copy of this article now, so that you can get the information off of it as you need it.

$$
REQUIREMENTS: You must have a confirmed PayPal account. If you do not have a PayPal account you can go to www.paypal.com and follow the instructions to set up a free account. In order to place the initial $6 into your account, you will have to confirm your bank account with

PayPal (which may take a few days). PayPal is 100% secure and is used my millions of people world wide. Confirming a www.paypal.com account simply means (1) PayPal will first ask you to confirm the email you used to sign up your PayPal account by sending you an email with a link for you to click to that email. As soon as you click that link your email is confirmed. (2) PayPal will then make two small deposits into your bank account if you set up your PayPal account with a checking or savings bank account. Or PayPal will make two small deposits to your credit card if you set up your PayPal account with your credit card. Then after a few days (it takes up to a few days for these deposits to appear in your bank account or on your credit card statement) then after a few days you go back to the www.paypal.com website and sign in. Then you click where it says this account is not yet confirmed. A screen will pop up that gives you 2 boxes to fill in. You then enter the numbers of the 2 small deposit amounts (two separate 2 digit numbers) that were deposited to your bank account or credit card. Now you have a working and confirmed PayPal account and can receive payments.

$$
[STEP 1]
Send, though PayPal, $1.00 to each email on the below list. Make the subject of the payment "Email List" and in the comments, write "PLEASE PUT ME ON YOUR EMAIL LIST." What you are doing is creating a service by this - and best of all you are not giving your address to anyone you do not know. THIS IS ABSOLUTELY LEGAL!! YOU ARE CREATING A SERVICE. Here are the latest PayPal e-mails on the e-mail lists:

1. Kobragt500 @aol.com

2. youngman2006 @ntlworld.com

3. Lenny8971 @aol.com

4. chrlwoods8 @aol.com

5. cerebayretailer @msn.com

6. drewsaelens @msn.com

www.paypal.com

Subject of Payment: ***Email List***

Comments: ***PLEASE PUT ME ON YOUR EMAIL LIST***

[STEP 2]
Now take the #1) email off the list that you see above, move the other addresses up one (6 becomes 5 & 5 becomes 4, etc) the put YOUR email address (the one used in your PayPal account) as #6) on the list. **MAKE SURE THE EMAIL YOU SUPPLY IS EXACTLY AS IT APPEARS IN YOUR PAYPAL ACCOUNT**

[STEP 3]
Change anything you need to, but try to keep this article as close to original as possible. Now, post your amended article to at least 200 newsgroups, message boards, etc. (I think there are close to 32,000 groups) All you need is 200, but remember, the more you post, the more money you make - as well as everyone else on the list! In this situation your job is to let as many people see this letter as

possible. So they will make you and me reach!!!! You can even start posting the moment your email is confirmed. Payments will still appear in your PayPal account even while your bank account is being confirmed.

$$
DIRECTIONS ON HOW TO POST TO NEWSGROUPS/MESSAGE BOARDS.

[Step 1]
You do not need to re-type this entire letter to do your own posting. Simply put your CURSOR at the beginning of this letter and drag your CURSOR to the bottom of this document, and select 'copy' from the edit menu. This will copy the entire letter into your computer's temporary memory.

[Step 2]
Open a blank Notepad file and place your cursor at the top of the blank page. From the 'Edit' menu select 'Paste'. This will paste a copy of the letter into notepad so that you can add your email to the list.

[Step 3]
Save your new Notepad file as a .txt file. If you want to do your postings in different sittings, you'll always have this file to go back to.

[Step 4]
Use Netscape or Internet Explorer and try searching for various newsgroups, on-line forums, message boards, bulletin boards, chat sites, discussions, discussion groups, online communities, etc. EXAMPLE: go to any search engine like yahoo.com, google.com, altavista.com, excite.com, then search with subjects like "millionaire message board" or "money making message board" or "opportunity message board" or "money making discussions" or "business bulletin board" or "money making forum" etc. You will find thousands and thousands of message boards. Click them one by one then you will find the option to post a new message.

[Step 5]
Visit these message boards and post this article as a new message by highlighting the text of this letter and selecting 'Paste' from the 'Edit' menu. Fill in the Subject, this will be the header that everyone sees as they scroll thru the list of postings in a particular group, click the post message button. You're done with your first one! Congratulations! THAT'S IT!! All you have to do is jump to different newsgroups and post away. After you get the hang of it, it will take about 30 seconds for each newsgroup! **REMEMBER, THE MORE NEWSGROUPS

AND/OR MESSAGE BOARDS YOU POST IN, THE MORE MONEY YOU WILL MAKE!! BUT YOU HAVE TO POST A MINIMUM OF 200** That's it! You will begin receiving money within days! **JUST MAKE SURE THE EMAIL YOU SUPPLY IS EXACTLY AS IT APPEARS ON PAYPAL.**

Have fun!

"Their system uses repeaters placed at every one kilometer, (0.62 miles) and requires power lines to be modified to reduce interference with the data signals. The estimates were based on computer models, and that the data speeds available in a real-world version would depend on how many repeaters a power company used."

Nothing like trying to use something intended for one use for some other unrelated use. Why would any fool want to put high-speed transmission data on an unshielded single wire feedline that travels for miles in a hostile communications environment? One would think the idea wouldn't get off the professor's desk. Maybe PhD's should harvest rice six months each year to find out what the real world is all about?

> fluctuation of all signals will be wider. Myself, I've never been
> afraid of automatic circuits, but often I find they are marginal to my
> interests and for weak signal detection, I follow the conventions
> you've offered.

CL writes Ah yes AGC can cloud the issue -- using fast AGC can provide a
greater amplification of the noise (between words) than the signal (if the
signal is strong enough)

But on the other hand AGC can be a big noise reducer if used properly.
Tune in a strong SSB signal on 40M or 80M, with fast or no AGC -- assess the
noise between words. Now use slow AGC and listen to a greatly reduced noise
level (between words)

That is why I advised the original poster to use no AGC when assessing the
two different antenna conditions

But I agree -- use AGC as appropriate.

New operators are inclined to set the RF Gain to max, to read the S-meter. But the technique of increased AF Gain and reduced RF Gain with no AGC is used by many experienced ops. Disadvantage is, of course, when a big gun jumps on the frequency while you are set for no AGC -- ouch my ears. Maybe a small price to pay in order to pull out that weak one.

Also for weak signal detection, listening with headphones can make a big difference in comprehension as compared to listening to a speaker. Using the above techniques and head phones, top notch CW operators can copy code even when the signal is about the same as the noise.

I can't do this though (;-(
old ears I guess (;-)

fractenna@aol.com (Fractenna) verbositized:

>As a 12 year member of AOL, I note that the world's largest ISP has made a
>decision to drop newsgroups from it's service.

Then you SHOULD remember when AOL was TOTALLY IN-HOUSE, the only
connect to the outside world at all was the ability to send e-mails
out-of-house. Then they started playing with home-brew web browsers
that rarely worked and were constantly being updated to fix the many
bugs in the programming.
It was not until AFTER they finally had a very limited web browser
that they decided to finally allow access to USENET Newsgroups.
It was the LAST external source of information they allowed, so
obviously it will be the FIRST to be cancelled as they try to revert
back to their original In-House state.
They have already screwed up e-mail to the MAX, so that it is almost
impossible to e-mail an AOL member.

I'm surprised they kept you suckered in for so long.
The WISE found REAL ISP's that did not price gouge them and who
offered many more valuable services.

How about a compromise? Split the difference.

1. Tune low, measure the length.
2. Tune high by trimming, measure the new length.
3. Solder a piece of wire equal to the difference in leg lengths to one
leg only.

Time was when "REAL ISP's" all offered usenet/netnews
service. Now my "REAL ISP" has dropped its newserver
access. Netscape doesn't offer it except through Google.
Incidentally, Google's upgraded newsgroup interface
isn't half bad. But I suspect they will start charging
a fee for its use sometime in the future.

Hi OM,

Well, back when I was in college physics (before the flood), my
professor put me and a buddy on a task to build the perfect detector.
It correlates perfectly with your advice to use headphones.

He had us build a Synchronous Detector (not a simple device to
construct from tubes and at 455 KHz). Some may be familiar with this
form of detection, and yet they may be ignorant of its best
implementation. For others, this kind of detector is also found in
color TV detection and color information separation. Often the block
diagramming or circuitry is described in terms of I and Q paths. I
won't go into the particulars of design, but I will offer that these
two separate paths when broken out to separate Audio channels, and
then fed to stereo head phones, they offer an unique signal hearing
experience.

Basically, the entire two channel system is completed by the brain
combining phases and providing a perception of the wanted signal being
"heard" in the middle of your skull, while interfering off-frequency
signals are perceive off to one side or the other. In a sense, you
hear an enhanced signal through phase reinforcement.

IA few years ago, I had to use an indoor antenna on 80 and 160 metres due to covenant restrictions (I put up a small vertical outside for 40-10 metres. No one noticed it so no one cared.) The indoor antenna started at the floor of a bedroom closet, ran up into th attic to the dizzying height of 15 feet, and went horizontal for about 30 feet ending in a huge capacity hat that I constructed at the gable end of the attic. It resonanted at about 2.5 MHz and I fed it with an L-network mounted on the floor of the closet, using, for a ground plane, the heating ducts, copper plumbing and a few extra wires in the basement. It worked as well as most folks' outside dipoles on 75-80, and on 160 , on several cold crisp winter nights, I was able to work into the UK and France on CW. Yes, when I hit the key, the lights on the Christmas tree would glow--even though the lights were't plugged in! Anyways, moral of the story is don't limit yourself to 2 metres. Put something up. You'll be pleasantly surprised by what you can work with an indoor antenna. 73. Harry MacLean, VE3GRO, London, Ontario, Canada, e-mail MacVE3GRO@aol.com.

Hi Gary,

Is there any irony in the convergence of SOL members logging in here with off topic comments to offer that because of off topic comments the news service is in decline?

Perhaps it is more an issue that the walls being built are not to keep people out, but to keep them in. This comedy must at some point include watch towers behind barb wire.

The greater irony is that the bright star of the dot.com firmament, SOL, no longer appears on the company mast head of Time-Warner to continue their embarrassment. Talk about a disappearing act!

Without dropping 200 or so on Commercial. Im in the process of trying to find a better 80 and possible 160 antenna for a short lot. Right now I have a G5RV that goes from corner to corner. I have just about 110ft from corner to corner on the long side.

Ive been looking at Windoms, but would have to modify it, and Im not sure.

SOOO, what other antennas are I missing. Warc, plus 40/80 are definite but would like to play with Top Band too.

BEAR in mind, I dont have a big tower to put a sloper or other on to. This is from a tree (50Ft) to a Mast I put up (20ft)
Thanks Scotty N7HJ

It may be possible to get even more improvement by slowly adjusting the
frequency setting of the Steppir over a wide range. The would steer its
nulls around and let you find the best s/n.

Ok, so what would you reccomend for a battery that sits indoors (but in a battery box if need be) and would be on float most of the time, with deep discharge at say C/10 or C/20-ish rates?

A sterling example of why "the biggest" is immediatly suspect. I got myself online before there was an AOL, back when ISPs were not in the advertising biz and when all they provided was getting you "plugged in" and the rest was on you. It was upon us to pick and choose our e-mail, browser and newsreader clients, etc. The downsides of course were the limits on access hours/day, reliability was lousy and as often as not dialing the POP sites were expensive long-distance phone calls. But it worked. Clean, simple and very effective. Then along came goofy AOL with it's bottom line objective of opening up the Internet for the incredibly dumbed-down and clueless masses so that they could control and micromanage their online lives . . . I've used AOL as a "guest op" here and there. I can't even start to imagine how or why you people put up with their garbage.

One of my brothers found a use for AOL though. He collected a 15 inch high stack of AOL CDs and made an interesting lamp out of 'em.

Not enough info to tell. You need to measure or calculate the input Z
of your transmission line with the two (or more) wire lengths and then
calculate the tuner loss for each case. This will depend of the
topology of the tuner.

Remember that as a general rule, the tuner capacitors are lower loss
than the inductors. I think that you will find that over this
restricted frequency range there will be little difference, although
with some weird line length, you might create a condition where the
tuner is quite lossy.

Rick - to open up more options, can you utilize ladder-line / twin lead all the way to the radio area or does your set-up absolutely need a coax feedline? I have seen commercial antennas (loaded dipoles) 110-120' that can be used for 160M up when fed with open wire that aren't too expensive. The ends can be dropped down for 5' or so at each end to fit into your lot.

Check out URL http://www.northwestantennas.com/ up here in Canada for one idea at $60-$70 USD, shipping included.

Also, your G5RV can be shorted out and used on 160M with a tuner. Good luck..... Al, va3kai

OK Jim, I'll accept you were an expert in the battery field, and your advice
is appreciated. How about just quoting some of your
manufacturer-recommendations for safe battery charging? You know, the kind
that are in large, bold print, usually in red ink, in both the battery and
charger instructions? "Cautions" and "Warnings", listing various types of
personal injury, or death, that can result from misuse or failure to follow

instructions. Unfortunately, these warnings don't travel around with used batteries and used chargers that sit in someone's garage for decades.

1516. How about a wire 1/4 vertical near a tree ???

Newsgroup: rec.radio.amateur.antenna
Date: 2005-01-27 21:20:15 UTC
From: "M. van Wijk" <"pa5mwremove all between"@home.nl>
Message-ID: <ctblug$8st$1@news1.zwoll1.ov.home.nl>
Source record: 82907

Hello,

I just moved to a new location. My backyard has some 20 trees spread around at a distance of 5 to max 10mtrs between each of them.
I would like to opt for a full size 40mtr(7Mhz) vertical and have (only)the 2 following options her:

1) full size 1/4 wire vertical inside fishing pole, mounted in a tree at a foot height between 7 and 10mtrs from ground level. Some 4 elevated radials will be added.

2) full size 1/4 wire vertical at ground level, parallel to a tree at a distance of 0.5 till max 1 mtr. Ground screen will be some 16 pcs of wire buried in the surrounding ground.

I have no clue about any effects of trees here. They are not pine trees. There are lots of other parameters in the whole picture, but the trees is a totally unkown factor for me.

Please share me your experiences.

Thanks in advance.

I always operate CW this way --- always have since my first S-85 receiver.
I fully agree that it improves CW readability. On SSB, I sometimes turn the
RF down (on my Omni 6+) until the meter reads zero on the background noise.
This seems to help a little, but not to the extent it does for CW.

The absence of a full-time RF gain control has caused me to delay ordering
an Orion; I am still thinking about it.

Excellent point. That might account for my "odd observation". I have
usually seen the effect when noise levels are high -- mostly due to storm
activity -- and the noise is probably directional in these cases.

Anyone out there know of any decent solution to getting 160M working in a mobile? The application is a semi-truck. I've got the Iron Horses for 75, 40, 20, 15, and 10M, but I'd like to work something out for 160 meters that will work on the truck.

I know I'm going to take an efficiency hit, but you're doing that for everything except 10M on a Semi anyway.. Just so I can get a signal out there to be heard, in the off chance.

ANY suggestions or ideas would be greatly appreciated.

>is (at these freqs) no......

I use a multi-band dipole, but it is full length. I have about 130 feet of 75 meter dipole and 67 feet for 40 meters (the lengths may vary, but they are tuned to the SSB portions I use.) I feed them into the house via 75 ohm coax. The 40 meter elements hang about 6 inches below the 75 meter element. No tuner or other matching is necessary and the 75 meters band width is increased because of the 40 meter hanging below it.

This is the same style antenna I used for the first time as a novice. I have continued to use it over the last 26 years.

If you are going to use a tuner for tuning the antenna to all bands, I would eliminate the traps altogether and tune down the 75/80 meter elements. There are several places on the Web that explain what lengths actually work best for all-band operation.

Someone has an Off-center Fed Dipole that they claim works really well for all bands and it is a bit shorter than the 1/2 wave 80 meter dipole. Look for Off center fed dipole and doublets in a search engine. I am sure you will keep yourself occupied for many hours reading various solutions. I am sure one of them will fit your need perfectly.

Good luck.

Big screwdriver with a proper top hat and a good impedance match at
resonance.
The resonant feed point impedance must be a bit less than 10 ohms.
I recall in QST a while back a guy who'd done WAS on 160 from his pickup, so
it can work.

And where, on a semi-truck, would you mount a big screwdriver with a
proper top-hat? I'm not discounting the suggestion, but at the same
time, I can't think of where I could possibly mount one.

I was thinking something more along the lines of a mono bander that I
could mount on one of the mirrors, that wouldn't be too large. Say,
something with a loading coil somewhere along its length, and something
that wouldn't be too expensive (Hopefully less than $50.00 US) to
construct. However, I'm not sure that's the best solution, either, which
is why I asked here.

A screwdriver is not in my near future. I'm recovering financially from
3 months off last year due to a gallstone the size of a golf ball, and
an accident in the truck earlier this month.

Thanks for the suggestion. Any other thoughts?

Hi Chris,

Is this a tractor/trailer rig? Put a monster whip up front and pull
it back to the trailer (where-ever) with a monster coil at the end and
make the trailer the -ahem- top hat.

Everything that could go wrong probably will....

That's a great idea.. A long wire along the trailer... It's a flatbed, too, so I could use the stake posts to hold PVC pipes for antenna supports... Hrm.. Now if only the AH-4 tuner for my 706 would do 160M, I could just set up the wire and tune it, much like I did with the one on the old truck.

I'll have to give that one some thought.

Thanks Richard.

1528. Ferrite bead balun for UHF?

Newsgroup: rec.radio.amateur.antenna
Date: 2005-01-27 23:14:06 UTC
From: MikeN <mnewman@clear.net.nz>
Message-ID: <kdtiv0ddt558fmhlfsb3ip324ssiq40ebh@4ax.com>
Source record: 82916

I've modelled a 70 cm Moxon rectangle - with impedance of 50 +j0, and F/B around 30dB. The cardiod radiation pattern is ideal for my application - a repeater on one side of the service area, co-sited with a 70 cm link repeater. The service area covers only about 25 square miles - filling in a local coverage gap. I need the rearward null of the cardiod to minimise interference problems with a co-channel repeater 85 miles away.

The antenna is balanced - so I need to decouple the coax feed line.

The obvious choices (at least to me) for feeding the antenna are:

1. Coaxial sleeve balun: this requires a bit of measurement and cutting, also waterproofing, and is not easy to fit in the physical arrangement.

2. Ferrite bead balun: dead easy to install, and doesn't compromise weatherproofness of feedline.

I have some ferrite beads which the supplier specifies as having 200 ohms impedance at 100 MHz, which snuggly fit on a short piece of RG-400/U coax connecting to the main LDF5-50 feedline.

But who knows how what impedance they represent at 70 cm?

Can someone tell me about the effectiveness of ferrite bead balun chokes at UHF, and how test this.

What other arrangements which would achieve the desired results?

Thanks

MikeN, ZL1BNB

==========

For design and performance of a 160 meter band vertical antenna, download program HELICAL3 from website below. There are other loaded vertical programs..

Use 1.5" or 2" diameter plastic pipe, with helical winding of thick enamel insulated wire, mounted on vehicle roof, as tall as possible, stayed, with short, top caapacitance tuning rod.

Range on 160m with a few hundred watts = 100 miles at noon on groundwave.

1700 miles on very quiet, wiinter nights at midnight via F-layer.

Chris's problem is that he has to keep the tip of the antenna below
about 13.5 feet from the ground to be legal with the various DOT's.

> reception than a resonant antenna?

There are several possible causes here.
Probably, on the design frequency, its antenna is probably matched to 50 ohms , for good transmission. A matched antenna does not necessarily give the best S/N for reception, and usually a mismatch does. Its hard to calculate.
One filing mentions the possible change in pattern, and therefore a possible change in S/N.
Suggestion- make a number of measurements, and if it hold up, send a note about it to QEX. Include as much info as you can, especially the SWR or better the antenna impedance on the different frequencies.

Chris
Must the antenna also only mount on the tractor?
I just thought of a multi-turn loop, corners as far forward and back,
wide as possible, above the cab.
Use a tuner and balanced feed.

Drop the ends of a half-wave dipole enough to fit the lot. You will loose a
little in signal, but probably less than in the matching section for a short
antenna.

Dear Mark,

I thought no one had many trees over there. There's a rumour that you
make shoes from trees. Can't be so - would be damned uncomfortable.

Anyway, trees are bad news for verticals. They absorb too much of the
energy - the closer you are to the tree, the more energy is induced in
the tree and dissipated as wasted heat. There is no data on this that
I am aware of, but I would say the effect is similar to that of
surrounding your antenna with the wood rafters and sheathing of an
attic.

My recommendation would be to get your energy running perpendicular to
the trees to minimize that coupling and hope for the best. In other
words, in your environment a poor dipole would be better than an
excellent vertical. In fact, that's usually my position even without
the tree problem - Hi!

That's an idea, but most balanced tuners I know of are manual only, and
it's hard enough keeping a 70-foot long, 80,000 lb vehicle on the road
without trying to tune, too..

Thanks for the idea.

Hi Mike,

Well, you are going to have to make up your mind. In one post you
want a simple instrument, in another post you are fishing for answers
with an antenna analyzer (but you don't have a FSM?). That seems to
me to be at least a 10dB variation in $$$. Now if the spec is that
loose, I can up the ante another 10dB to give you a direct reading
answer.

How much are you willing to spend?

Reg:

Thanks for this.. it'll help allot..

Question, though.. What should I put down for "earth electrode loss
resistance"? I'll be using the truck's body as the ground plane.

I'd just thought about doing this with a 2 foot (or so) 2 inch PVC pipe with end caps, feed point at the one end of the PVC, and a 102" whip out the other end. Now that I know this program exists, it's easier to think about! Since the SS whips are tapered, what would be a good guess for the diameter of it? Average it to 3mm? Or will it make that much of a difference?

Thanks

Source record: 82935

Thanks to everyone for the info. For the record, I'm going to leave the antenna tuned for 1.875 and use the tuner for those rare times when I go above 1.930.

Since I operate on 1.893 about 75% of the time (not using the tuner at all), I figure I'll be OK.

You don't have to use a balanced tuner.
Terminate the loop into the truck body.
What auto tuners cover 160?
I never checked.

The AT-180 does.. so does Alinco's long wire tuner (which can be made to
interface to my 706Mk][G).. There are others, I'm sure It'd be nice to
just press a button and tune the sucker, that's for sure. But I'd also
like to do it for as few dollars as I can..

I know.. bad form to reply to your own post...

Got something here I think will work...

Resonant at 1.903
h=.61
d=510 (around 2", plus the insulation thickness.)
n=28
w=3
l=2.49
r=3
e=5 ohms

Makes for a 4.6kHz bandwidth (not wide, but I knew that going into
this...) with an efficiency of 2.4 %.. 16.2dB down from "ideal", and
50ohms (or close) with a 4.1uF cap.

Of course, this is assuming that the whip doesn't have to be
perpendicular to the centerline of the coil. If it can be parallel to
the coil (perpendicular to the winds), then this might work... I hope.

I'm gonna play with it some more, and see what I can dig up.. Maybe a
larger coil form will give a wider bandwidth?

Try the vertical off the ground, keeping the base of the antenna and four radials about 3-4 meters off the ground. should work quite well and uses less radials. Theoretically you can use two radials (worth comparing, you may be pleasantly surprised).

Don't take me for an expert here, but I like the option number 2.
While the tree may have some effect, I don't think it will stop your
signal or cause so much loss you can't be heard. However, the more
radials, the better. Rather than the four above ground radials, the
16 buried may produce better results.

I would never use an aircraft battery for anything other than in an
aircraft. For weight savings aircraft everything is made as light as
possible consistent with safety and operation. Light weight and battery
capacity are completely at odds with each other.

Great stuff...thanks Richard!

Ive got a homemade tuner going at present that is doing a good job of taming all the signals that my 70ft. wire is getting....so things are really getting fun! (even the hour putting up the wire early Sun day morning, about -35 degrees.. ;-)

Thanks again

Mike

I have a handheld tranceiver (VS VXA-700) and I'd like to mount a good antenna on my pick-up. Can you point me to a good retail product? My pickup is an 02 F150. I'm thinking I'd like to use one of the stake pockets as a mounting point? If I need to compromise on antenna band width, I'd lean toward best reception on 2m band.

Anything hidden pitfalls I need to be aware of?

Thanks,
Carl

Hi Richard

Well that calorimeter is a simple instrument, but how can I apply my
simple knowledge to give a meaningful result.

Would it go something like this?

1. Take a polystyrene cup packed in a piece of polystyrene foam,
and with a polystyrene lid.

2. Pass a piece of thin - say RG174 - coax through the lid.
Run the centre conductor through the bead and wrap back around bead
and solder to to braid.

3. Immerse the bead in say 150 cc of H20 - initially at freezing.
Use an in-glass thermometer to measure temperature. Apply some 70 cm
rf from my handheld (on low power).

4. Measure the rf voltage across to the coax at the ferrite bead
using a simple diode detector - calibrated to give RMS applied
voltage E.

5. Measure the temperature rise with time until a steady state above ambient temperature is reached.

6. Replace the ferrite bead with a resistor, and apply DC voltage same as E to get the same temperature rise in the same time period. Change the resistance value as necessary to get the same temperature rise over same time.

7. Dummy load is now dissipating the same power as the ferrite core did.

8. Calculate the impedance from Z=E^2 / W.

9. Repeat to see if results are reproducable.

10. Substantial inaccuracy will result from differing thermal mass of bead and resistor. Bead is 29mm long, with 16mm OD, and 8mm ID.

11. So what should I do to refine this procedure?. What am I missing here?

I'd like your comments.

Thanks

MikeN, ZL1BNB

1560. Isotron antennas

Howdy y'all.

I had to finally try one. Got a 40meter Isotron, put it up at about 15'. It does work.

Not sure how well, but it sends and hears. Worked a guiy in Cuba from Awstin, TX and a K6 on CW. Not the greatest reports.

Anybody else tried them?

Just curious. Please no flames. This was idle curiosity.

Make Tons Of Money Fast!
I was browsing through newsgroups, just like you are, and came across an article similar to this that said you could make thousands of dollars within weeks with an initial investment of $6.00! I thought," Scam", but I was curious, so I kept reading. It said : send $1.00 to each of the 6 names and address stated in the article. Then place your name and address in the bottom of the list at #6, and post the article in at least 200 newsgroups. (There are thousands) No catch.
I was skeptical and worried about the legal aspects of it all, but checked it out with the U.S. Post Office (1-800-725-2161) and they confirmed that it is legal! I invested the measly $6.00. GUESS WHAT!!... Within 7 days, I started getting money in the mail! I figured it would end soon, but the money kept coming in. My first week, I made about $25.00. By the end of the second week I had made a total of over $1,000.00! Third week I had over $10,000.00. Fourth week and I've made a total of just over $42,000.00! How and why this works.. Make a copy of this NOW, so you can get information off of it as you need it.
1: Get 6 separate pieces of paper and write the following on each piece "PLEASE PUT ME ON YOUR MAILING LIST." Now get 6 US $1.00 bills and place ONE inside EACH of the 6 pieces of paper so the bill will not be seen through the envelope to prevent thievery. Next, place one paper in each of the 6 envelopes and seal them. What you are doing is creating a service by this. Mail the 6 envelopes to :
#1) Gary Wilson 21 Weston St. Apt-315 GrandRapids, MI 49503
#2) Fred P.O. Box 25534 Yuma, AZ 85367
#3] Jason Calbourn 452 Kuhn Street Pontiac, MI. 48342
#4] Natalie Sanderson 114 Oak Hereford, TX 79045
#5] Demetria Garcia P.O. Box 421 Richgrove CA 93261
#6) Thomas Ledbetter 1401 E.Bristol St.Apt. A202 Phila Pa 19124
2: Take the #1 name off the list that you see above, move the other names up (6 becomes 5, 5 becomes 4, etc...) and add YOUR Name as number 6 on the list. Change anything you need to, but try to keep this article as close to original as possible. Now, post your amended article to at least 200 newsgroups. (there are close to 24,000 groups) Just need 200, but remember, more posting, more money.

Per your earlier use of an RF detector, you have to first consider the conversion factor (was the meter peak reading or average?). Why bother, you already have a power source (the HT) you already have a detector (your same simple detector). No conversion necessary.

>8. Calculate the impedance from Z=E^2 / W.

Hi Mike,

Step 8. is unnecessary given step 7. You only want to know the ferrite R which is directly obtainable from the Resistor setting (or Resistor choice). You don't even need to compute power anymore as that has fallen out of the equation in the method you describe - which, by the way, is a good example of crafting a solution. It shows you simplifying my stark description of caloric measurement to instead engage in bolometrics (comparison of heating). This method is probably superior in simplicity and results would easily be within 20% (which is not shabby for UHF).

Your introduction of a resistor is also an example of what Metrologists call a "transfer standard." It is an example of using the "substitution method." Your only concern is that the resistor present a true resistance and not some complex Z. In other words it should match the feed, and not offer much stray X. With that said, it becomes a tougher problem (but then you needed to do the same thing with the actual Z of the ferrite) that is, matching. It is arguable that they would both mismatch equally (and given the Power term is canceled, match is not particularly necessary). Everything here depends on your re-obtaining identical indications.

This discussion reveals the cost of absolute determinations.

To increase the success it behooves you to up the power to cut down on environmental temperature biasing the experiment (also cuts down on other subtle influences like the difference in mass of heated

samples).

There are also indirect methods which can tolerate far more imprecision. Ferrites are composed with bulk properties that have frequency dependencies. These properties, however, vary quite smoothly and slowly across great ranges of frequency. They also exhibit distinctive family properties. The different grades of Ferrites react with peak Resistances in different bands, but for our purposes one family of Ferrites can be quite useful across a significant percentage of bandwidth. Consult:
http://bytemark.com/products/ferrmat.htm
Unfortunately, Bytemark.com has fallen short of complete documentation. They offer a link to illustrate Z over F, but it is a dead link (and has been for years).

However, by this one page alone you can discern the family characteristics I speak of. Your best hope is that your beads are composed of something like type 43 or 64 instead of type 61 or 73.

An indirect method would be to measure the bead in series with a good resistor - at two or three frequencies. HF, VHF and UHF would be eminently suitable. If the bead shows a higher R at UHF, this trend would tend to support an assumption you are have a suitable material type. Both types 43 and 64 should exhibit useful resistances in both bands. The slope frequency characteristics of these materials easily span both higher bands.

Let's put some useful context to this. For any bead that snuggly fits over the jacket of an RG-58 cable the following Rs should be seen for:

Material HF VHF UHF
75 ~20 ~10 ~5
73 | 77 25-30 ~20 ~15
43 ~20 ~32 ~30
64 ~5 ~30 ~35

This should put material identification within reach.

The MFJ antenna analyzer only reports SWR at 70 cm, and any value >5 is just reported as ">5". So I don't think it would be useful for this measurement, except maybe as described below. Even at 2 meters, you'd have to be careful to keep the length of the wire containing the beads at a small fraction of a wavelength. That might not be possible with something like a complete W2DU balun -- you'd probably have to measure a smaller number of beads and extrapolate.

One thing you might try is this:

Make up a test jig from a female connector (BNC would be best), a piece of copper clad board, a piece of small diameter coax two or three inches long, and a small 47 or 51 ohm resistor. (You'll probably have to use something smaller than RG-58 because you'll have to bend it into a loop. But it's important that it be considerably shorter than a quarter wavelength long.) Solder the BNC connector directly to the ground plane, and connect the coax to it with extremely short leads. Call this end 1 of the coax. Solder the resistor across the other end of the coax, end 2, with extremely short leads. Hook the MFJ to the test connector with an ordinary coax patch cable and measure the SWR at the frequency of interest. Unless you can get a reasonable SWR (well below 5:1) with this setup, there's no point in proceeding. If you can, then try touching the shield side of the short coax to the ground plane. The SWR should remain reasonable.

If you got a reasonable SWR with this setup, the next step is to touch the *center* conductor of end 2 and attached resistor to the ground plane at the same point as the connector is soldered. Notice that the SWR skyrockets -- this is simulating a worst case situation for a balun. (If the SWR doesn't skyrocket, your coax is too long to do a valid test.) Now add beads to the outside of the short coax and repeat the test, that is, touch the center conductor of end 2 to the ground plane at the connector. If you can find a combination of beads that'll drop the SWR back down to within the range of the meter, you have enough impedance for a balun. You could probably get by with less, but any combination of beads that passes this test will surely be enough.

Mark,
I had a 40 m 1/4 vertical hanging from a tree branch. Feedpoint was about 8 meters above ground with 4 radials. On the average, performance was equal to the 40 m dipole at 15 meters. It was about 3 meters from the tree trunk. If you are going to have buried, or ground mounted radials, you would need a lot more than 4. Oh, BTW, the tree is 25 m tall.

> calculate.

Although this can be true at VHF/UHF, where the receiver noise dominates, it's not true at HF, where the observation was made. At HF, external noise dominates, so the quality of impedance match makes no difference in S/N ratio.

> One filing mentions the possible change in pattern, and therefore a
> possible change in S/N.
>. . .

I'm certain that's the explanation (assuming it's not a mistaken subjective observation) -- the noise is coming pedominantly from one direction, and by tuning the antenna a pattern null was created in that direction. Signals from other directions are then stronger than the reduced noise.

I've often directed my 40 meter 4 square array toward the southwest to put a null toward the U.S. Midwest and Gulf Coast, where a lot of thunderstorms occur in the summertime. VKs jump out of the noise when I do that. Rotatable loop receiving antennas are often used in the same way, to null out noise coming from one direction.

Are the "iron horses" like hamsticks, but another brand? What I would
do is
get another one. Doesn't really matter what band, but I would get the
one
that is tallest physically, and uses a tall "stinger" whip. Then strip
it down,
and make a "plastic bugcatcher" with a new wider coil.
I use this type of antenna myself, except that mine is 80-10 with a
coil
than can be tapped for each band.
For a 160m whip with no hat, coil position will have a large influence
on
efficiency. So if say you used a junk 6 ft tall hamstick, I would wind
the
new coil at the top of that glass whip, and then clamp a tall "4-5 ft"
whip
to the top of that. Use a thin plastic form to wind the coil on. On
mine, the
the coil is wound on an appx 3 inch plastic tube, and is capped on each
end
with a plastic peanut butter jar cap. Melt a hole large enough for the
glass
whip to insert snugly up the middle of that coil form, and apply some
glue,
etc to hold it in place. For an 80m antenna built in this manner, you
would
need appx 80-85-90 turns or so, plus or minus...That is about a foots
worth of
winding on the 3 inch form, if the windings are made from an insulated
wire,
say 18 gauge or so.

The insulation will add some spacing to the windings, which is good..
My antenna is a 6 ft glass stick, with the coil at the 5 ft level. The
coil
is about a foot tall, end extends to the top of that glass mast. I use
a 5 ft
stinger whip, so my total length is 10 ft, or appx 3.3 m.
To use 160m on the same stick, your coil will be slightly more than 3
times
as long, to keep the same winding ratio. So if say on 80, the coil was
at the
5 ft level, on a 6 ft "1.5m" base mast stick, ".3 m coil length in
Reg's
vertload program", on 160m, the coil would be 1 meter long, and the
bottom
of the coil would drop to about the .8 m level, but still extend to the
top
of that glass mast. Thats a pretty tall coil, and will have some weight
with
all that wire..So I wouldn't get carried away with wire gauge...I'd use
16-18
gauge or so...
Anyway, thats about the cheapest way to make a 160m antenna that will
work
halfway well. It's a bugcatcher electrically...Of course, you will need
a
matching device..

To see a picture of mine, go to... http://web.wt.net/~nm5k/fd03-1.jpg
Thats about the only pix I can dig up that shows the whole antenna.
It's on the truck utility bed, about 4 ft off the ground at the base...
Even with the distant picture, you can make out the stinger whip at
top...
Will give you an idea what I'm talking about...
That one is 10 ft total. The glass whip was a 6 ft 20m hamstick, that
was
stripped of it's top coil. The stinger whip is 5 ft tall. You can see
the
homebrew coil at about the 5 ft level, extending to the top of the
glass
whip. The stinger is held on by two small hose clamps.
That's the 80m coil, which is nearly a foot tall. If you converted that
to
160m, the base of the coil would have to drop 2-3 ft, in order to have
the top
of the coil at the top of the glass stick.

> >>
> >>I know I'm going to take an efficiency hit, but you're doing that
for
> >>everything except 10M on a Semi anyway.. Just so I can get a signal
out

> >>there to be heard, in the off chance.

Yep...Using vertload, my antenna has about a 14.7 % efficiency on 80m, using
6 ohms as the ground loss number...On 160m, using the described 160m coil, and
same overall length, ground loss number, efficiency would drop to about 2.07 %
.. But, thats the way the ball rolls....It will still work...
I've worked many 160m mobiles..
A small amp would help...
I think one of the "hamstick" type companies makes a 160m "hamstick", if you
don't feel like making one...
One thing to remember....On 160m, ground losses will almost certainly overshadow
coil losses, so trying to make a super duper efficient coil, with real thick
wire, is generally a waste of time. Always use the longest stinger you can get
away with..I also have a solid 3 ft base mast that I can add, and make the
antenna longer "13 ft" and more efficient. In that case, the coil is 8ft up,
instead of 5 ft. Efficiency jumps up a good bit. It's not the prettiest thing,
but it works real well on all bands 80-10. And the best part was it didn't cost
me a dime. There is a black wire that taps the coil, but you can't really see
it in that picture. I also would like to make a 160m antenna, and might just
make me one like I described. I'll probably have a stand alone 160m antenna,
and go back to that one, on the other bands. I have a quick disconnect.
MK

BTW, if you are curious...That truck is my 68 F-250...It's kinda old...
I now also have yet another old ford..."74 F-100" It's got a camper also...
I'm trying to decide where to mount the antenna on it...Not as easy as that 68.
..I'll probably have to install a ball mount on the cab on the other truck...
I have a thing about old trucks...Kind of an illness...:/ I may eventually swap
one out, and buy another small car...Can't decide which one I like best though..
That 68 in the pix has nearly been rebuilt mechanically...New engine, front end,
etc, etc, etc...Needs to be repainted though... But the 74 is a bit

smoother,
being a 1/2 ton, instead of a 3/4 like the 68..Maybe better for long
trips.
The camper is a bit bigger and about a ft taller on the 74 also...
Yes, we have newer cars too, but I don't drive them too much
myself...:/
I like my "war wagons". People stay out of my way...

Mark:

Great idea...

In fact, the semi I'm planning to put this on is a '97 Ford LTLA9000. Only 872,722 miles on it. Just had the motor rebuilt, so it'll be good for at least another half a million. This was my first truck. I'm planning on keeping it until I retire, then turning it into a motor home.

The vertload program is quite interesting. It shows I can make an antenna with twice the efficiency of a base loaded antenna with similar dimensions, and I can tailor it to the truck for where I can mount it, and all of a sudden new mounting possibilities are popping up.

I took the fairings off the truck awhile ago, and the bolt holes on the fuel tank straps are still there for the fairings. It would be quite simple to weld up some angle-iron to make a mount for this, and keep the feed point low to the ground, so I can have a longer whip (higher efficiency! Yay!) on top of the load coil.

What I've got figured here is a 2 foot long, 1 inch OD copper "mast", a 1 meter (3 feet, 3 inches), 3 inch OD coil form, and a 78 3/4" whip, which should be resonant close to 1.903 with a 3.81% efficiency. Total overall height of the antenna is 3.61M, or 142 1/8", or 11' 10 1/8", which leaves me a little over a foot and a half to play with. Good deal.

Reg's vertload program (THANKS REG!) doesn't show a 2:1 SWR bandwidth, so I'll have to try it to see what the bandwidth will be. I really only need it to handle the width of an SSB signal (3 kHz), with some "wiggle room" to move up or down a few KC's for an SSB net I want to check in to during the winter nights. I have an AT-180 tuner I can use to match it down to "usable".

I'm going to play with the numbers a bit to see where I can move things around to get even better efficiency, then I'm going to build the sucker when I have it where I want it.

The really good news here is that I can build this thing for just a little over $20.00, which is exactly where I want it to be. Of course, I won't get around to building it until this summer, but it'll be ready for next winter's nets..

I just wish Reg's program would show a 2:1 SWR bandwidth (or a 3dB point bandwidth!).. that would be a godsend to those of us who would like to build some of these for SSB use.

Just thought I'd share.. This is cool. If I'd known stuff like this was
out there, I would have been playing with mobile antenna building a long
time ago.

It would be quite
simple to weld up some angle-iron to make a mount for this, and keep
the
feed point low to the ground, so I can have a longer whip (higher
efficiency! Yay!) on top of the load coil.....................

I'd ground that angle iron as well as possible. Myself, I tried angle
iron
one time, and it didn't work too well. I did run an extra grounding
strap to
body/frame. But it wasn't enough...I think the problem was from a lack
of
metal area directly underneath the antenna. That seems to be fairly
critical.
When I moved it from that angle iron support behind the back window,
and moved
to the side toolbox, the low band performance was much better. The top
of that
utility bed toolbox is a pretty good platform, and is a few inches
wide, and
naturally, pretty well grounded. Maybe use real wide angle iron??
I think you will find the bandwidth to be fairly narrow. And swaying of
the
antenna vs body of the truck will vary the SWR a lot at that low freq.
If it's
rigid, or guyed some way, it will be more stable. Should be plenty
enough for
SSB bandwidth, but for multiple freq's, I'd add extra taps on the coil,
to allow
you to move around. I have three or four 80m taps on my coil...
BTW, I was thinking about coil length vs wire size, and I may have been
a bit
off. An 80m coil of insulated 14 gauge would probably be about a
foot...
But 16 or 18 gauge would probably be a bit shorter. About wire size...
In the past I had made coils using larger dia wire thinking it really
mattered..
It does make a slight improvement, but I'd say slight...Hardly worth
the extra
weight...I made one using thick 14 gauge, and I can't tell a heck of a
lot of
difference compared to 16 or even 18 gauge. I think my present coil is
16 gauge
wire. That antenna is *light*. About like a fishing rod and reel. Using

thick
wire will make the coil much heavier, and then you have to worry about
it overly
swaying, unless guyed. So I don't use overly thick wire anymore. If I
make a 160
antenna, it will probably be 16 gauge...Maybe even 18...
If you mount the antenna low, it does increase ground loss, but I think
getting
the coil that much higher from the base *should* override the increased
ground
loss. Or as good as I can calculate anyway...I've never actually
mounted one
real low yet to compare..I do have hitches...Maybe I could try an
experimental
antenna on my bumper/bumper hitch...Would give me about a 3 ft longer
base under
the coil, compared to it's current mount on the toolbox.
Yea, vertload is pretty handy...I think probably the "Reg" program I
use the most
out of his vast collection. But I've been running these "plastic
bugcatchers" for
years...Since about 1990 I guess...I like the light weight. I've got a
"real"
80 m bugcatccher coil, and just that coil alone probably weighs 5 times
the total
weight of that 10 ft antenna I have. It's heavy and requires heavy
hardware to
support it. But heavy hardware doesn't "talk" any better than light
hardware..:/

I'd just do what most with CBs in pickups do - snake the coax out through a window and put a mag mount on the truck roof.
On-glass antennas are inefficient.

You might consider a simple inverted L given all the trees you have available. Build a very conventional half-wave coax-fed 40M dipole. Suspend half of it (35 feet long?) vertically with the lower end a foot or two above the ground from one tree then pull the other half more or less horizontally to another tree. Pull the coax away from the elevated feedpoint toward the Radio Room. Trim wires to resonance. No messy radials needed and most likely you wouldn't need a tuner or "tuning network" either. It would be just a standard inverted vee rotated 45°. Half-wave inverted Ls without radials scream, been there, done 'em.

Research on the subject done by the U.S. Army years ago determined that trees have no measurable effects on HF antennas. Trees do have an effect on vhf/uhf antennas. There was a thread in this NG in the past which addressed the topic in sdome detail and which is probably still archived. Run a search on "Do Trees Absorb RF?"

We did once erect exactly the same antenna. It was about 1 S unit worse than
2x 17 elements F9FT yagi, tested on RX only and for

1 hour when we hastily dismantled it due the snow blizzard :(. OTOH, -1 S
unit on 34 el yagi is nod bad for piece(s) of wire...

Source record: 82963

Chris,
Diameter of whip or loading rod is not critical. Enter average diameter over its length.

If not stated, bandwidth is between 3dB points when transmitting. When receiving, bandwidth is broader, say the 2 dB points, because the receiver input resistance damps down the very high antenna Q.

Earth electrode resistance depends on size of vehicle and type of soil under it. For a mobile home enter 3 ohms. For a volkswagon beetle enter 14 ohms.

A larger coil form will give a narrower bandwidth. Double length and height and for the same inductance (fewer turns), coil Q will also be doubled. You can't have high efficiency without high Q and narrow bandwidth.

If a flexible whip is used, to reduce overall height it can be curved backwards in parallel with the vehicle's roof. This also allows fewer turns of thicker wire on the helix and a higher coil Q with greater efficiency. There will be an overall gain but not so great as if the whip is vertical throughout its length.

Leave a gap equal to helix diameter between the bottom of the helix and a metal roof.

The helix is in fact the L&C Z-matching coil. On 160m, in order to resonate with its own self-capacitance, it needs a large inductance. There will be several hundred turns. Therefore, to have a loss as low as possible it has to be physically large. The only space available is in the antenna - and that's why it's there.

Ignore silly irrelevant done-to-death arguments about whether the current at one end of the helix is or is not the same as the other.

The most important dimension of short verticals is overall height. Next comes physical size of helix. The fatter it is the better. Obesity is not a problem. Only the wind.

Precisely.
If you were to store a battery array indoors you wouldn't want hydrogen venting.
Or would you?
;^)
(Got a match?)

I went to SLA batteries in my Baron because of the greatly reduced corrosion.
Aerobatic folks like 'em 'cause you can fly inverted without making a mess.

Hello,

Only for info, a dummy load with 20meters of bad quality RG58 coax cable
works great too! And you can also load the stuff with an LC resonnant
circuit that's smaller than an "isotron" and much cheaper.
Sorry but I couldn't resist... By the way, the miracle antennas only work on
27 MHz.

"By the way, the miracle antennas only work on 27 MHz."

I gotta remember that. That's great.
Thanks for the laugh.

Mike

I'll top post this because it might not be appropriate for your situation.
I dont know what you consider "simple equipment" and I dont know what
equipment you already have. I'm a *do it yourselfer* and recently built a
simple slotted line from Home Depot tubing, and picked up a "very
affordable" ($25.00) generator and voltmeter ($20.00)at the TRW HAM swap
meet. This set up allows me to determine the impedance of the baluns and
dipoles I'm interested in at 137 MHz.
Iy may be that the slotted line would be more difficult to build for 432.
And the idea of constructing something like this isnt of interest to you.
But, it sure works well at 137 MHz for evaluating ferrite tubes.

Jerry

I also have recently moved to a new QTH. At my last, I was a devotee of ground mounted verticals with many buried radials. My main antenna there was a 42 foot vertical, with 48 buried radials, each about 50 feet long. This time, being older and less inclined to digging, and work in general, but still being a devotee of verticals, I decided to try a vertical dipole in a tree. It is 28 feet long (tall), with the bottom end inches off the ground. The feed is in the middle with open wire line and an air-core balun. I use a "balanced balanced" Richard Measures-style "L" network tuner in the shack. The tree is a tall, skinny one, and the vertical wire is about five feet from the tree. I have been using it for about three months now, on 80 through 20 meters, mostly on my favorite, 40 cw.

I suppose at this point, following the pattern of others, I should go into a dissertation on signal absorption by trees, effect on pattern, effect of lack of radials, etc. I don't have any first-hand information on all that, but I can say that it works great for me. Performance is comparable to the aforementioned vertical at my previous QTH, considering that it is somewhat shorter. I certainly wouldn't advise against trying one because of seemingly adverse theoretical considerations.

Since he has room to hang a vertical, he can hang a slanted dipole
too. That would be a little directional but pointed in the right
direction it could be a great antenna.

>BPL may be yet another example.

During the dot.com boom, they were laying underground fiber all over.
(Downtown Seattle was especially bad, as the place was boomtown squared).
And most of it is lying in the ground unused because of "The Last Mile"
problem. It's as expensive to build the local distribution network to
get it from the fiber companies hub to individual customer sites as it
is to build the long distance network.

So along come the investor owned electrical utilities, who would just
love to have an unregulated business (so that they can get a more
profitable tap on the consumer's veins) yelling "WE CAN DO THAT".

With BPL they can set up in the business to compete with the cable and
telephone companies. So what if the stuff doesn't work, they can replace
it later with the same hardware the cable company uses. BAIT AND SWITCH.

And the regulated rate payers will probably foot a good part of the bill
because the whole company isn't making the profit levels the regulators
will allow.
